PNEUMOCOCCUS TYPE I PNEUMONIA

A STUDY OF ELEVEN HUNDRED AND SIXTY-ONE CASES, WITH ESPECIAL REFERENCE TO SPECIFIC THERAPY *

RUSSELL L. CECIL, M.D.
AND
NORMAN PLUMMER, M.D.
NEW YORK

The classification of pneumococci into specific biogic groups has transformed the medical point of view ith respect to pneumonia. Formerly, the physician ked: "Is it lobar or bronchopneumonia?" Today, he sks, "Is it type I, type II or type III pneumonia?" his change in attitude is fitting and proper, for the iology of a disease is of much greater practical sigficance than its anatomic characteristics. Furtherore, recent studies in this field have shown that the ree dominant types of pneumococci are not only biogically specific but, in addition, produce more or less haracteristic clinical pictures.

PNEUMOCOCCUS TYPE I PNEUMONIA

For the past ten years all cases of lobar pneumonia dmitted to the medical wards of Bellevue Hospital ave received careful bacteriologic study. During this ime, 1,161 cases of pneumococcus type I pneumonia ave come under our observation. In the present aper we subject this series of cases to clinical analysis nd report the results of specific therapy. This series ncludes thirty cases of type I pneumonia which have ccurred in children.

Method of Typing.—The mouse method was used as routine in the bacteriologic examination of sputum. Agglutination and precipitin tests were performed with he peritoneal exudate of the mouse, and at the same ime cultures were taken on blood-agar plates from oth the heart's blood and peritoneum of the mouse. In atal cases that came to autopsy, intravitam cultures vere controlled by postmortem cultures. During the ast two years, Sabin's[1] rapid method of typing has een extensively employed and has often made it possible to determine the pneumococcus type on the same lay the patient was admitted to the hospital. In addiion to the routine sputum cultures, many patients were subjected to blood cultures, and cultures were made from all pleural, pericardial and joint exudates.

Incidence.—Although pneumococcus type I is rarely found in healthy throats, type I pneumonia is the most prevalent of all the types. This fact is well brought out in table 1, in which the incidence of types in the adult series is listed. Of 3,662 cases of lobar pneumonia in adults, 1,131, or 30.9 per cent, were type I infections; type II was next in frequency, with an incidence of 23.2 per cent; type III caused only 11.9 per cent. The miscellaneous group of pneumococci was responsible for 34.1 per cent of the pneumonias studied in this series; however, a recent classification of this group into its component types shows that none of the twenty-three new types described by Park and Cooper[2] compare in frequency with pneumococcus type I as an exciting agent of pneumonia in adults.

Pneumococcus type I pneumonia is, therefore, the commonest form of lobar pneumonia, constituting almost one third of all the lobar pneumonias in Bellevue Hospital. The Bellevue figures agree closely with those of other institutions. For example, in Cole's[3] series of cases, 33.3 per cent were type I infections: in the series of Park, Bullowa and Rosenbluth,[4] 28.5 per cent were of this type.

Occurrence in Children.—It is interesting to compare the incidence of pneumococcus type I in adults with that in children. In a bacteriologic study of 147 cases of pneumonia in children, Plummer, Raia and Shultz[5] encountered only 14 type I infections, or 9.5 per cent. All but three of these occurred after the third year. From these figures it appears that type I pneumonia is quite rare in infants, while in children between the ages of 3 and 12 years it constitutes only 10 per cent of the total group.

Incidence According to Age.—In an analysis of 2,000 cases of pneumonia reported in 1927, Cecil, Baldwin and Larsen[6] pointed out that pneumococcus type I pneumonia was essentially the pneumonia of young people. In 585 cases of lobar pneumonia occurring in adults under 30 years of age, these investigators found that 246, or 42 per cent, were type I infections. In the present series of 1,127 type I pneumonias, 696, or 61.8 per cent, occurred in individuals between 10 and 40 years of age.

Clinical Features.—Pneumococcus type I pneumonia might perhaps be called the prototype of lobar pneumonia. With few exceptions, the type I patient gives a typical history, presents the typical signs and symptoms, and has a typical course. In a great majority of the patients, the onset is marked by a chill and pain in the side. The characteristic cough, accompanied by rusty sputum, soon makes its appearance. The temperature is prone to run along on a high plateau between 103 and 105 F., and in a majority of the cases the termination is marked by crisis rather than by lysis.

Complications.—The incidence of serious complications in 1,131 cases of pneumococcus type I pneumonia in adults is given in table 2. Other complications were: pleural effusion, 26 cases; jaundice, 19 cases; delayed resolution, 17 cases; cellulitis, 32 cases, and cardiac irregularity, 26 cases. Pneumothorax developed in 3 patients, lung abscess in 4.

Table 1.—*Incidence of Pneumococcus Types in Lobar Pneumonia of Adults Treated in Bellevue Hospital 1920-1930* *

Pneumococcus	Number of Cases	Percentage of Incidence
Type I	1,131	30.9
Type II	850	23.2
Type III	434	11.9
Group IV	1,247	34.1
Total	3,662	

* This series does not include cases admitted during the season of 1925-1926.

The common complications in children were empyema and otitis media. In 30 cases of type I pneumonia in children, empyema was noted in 5, or 16.7 per cent. Otitis media also occurred in 5 patients.

Bacteremia.—From 1926 to 1930, 470 type I patients were subjected to blood cultures and 90, or 19.2 per cent, showed a pneumococcus bacteremia. During the past year, blood cultures have been carried out as a routine procedure in 64 cases; 19 of these yielded pneumococci, an incidence rate of 29.7 per cent. This figure corresponds with that reported by other investigators.

Mortality Rate.—The death rate from pneumococcus type I pneumonia differs considerably in different institutions, depending particularly on the type of patient which the hospital admits to its wards. Figures reported by Wadsworth,[7] Locke,[8] Cole [3] and others show a mortality for patients with type I pneumonia not receiving serum of 15 to 25 per cent. In our Bellevue series of 412 cases without serum, in the period from 1920 to 1929, there is a mortality of 28.2 per cent.

Table 2.—*Serious Complications in Pneumococcus Type I Pneumonia*

	Number	Per Cent
	73	6.5
	20	1.8
	10	0.9
	7	0.6
	4	0.4
	5	0.5

The death rate for type I pneumonia in Bellevue Hospital has shown a steady rise since 1921, the second year of our investigation. The annual death rate of patients not receiving serum is given in table 3.

It is extremely important to note that in the period from 1921 to 1929 the mortality rate has increased from 20 per cent to 42.8 per cent. An explanation of this increase is not entirely clear; however, such factors as the influenza epidemic of 1918 and the increasing incidence of alcoholism seem to be important.

Table 3.—*Annual Death Rate of Patients Not Receiving Serum*

Year	Percentage of Mortality
1920-1921	23.8
1921-1922	20.0
1924-1925	26.4
1926-1927	30.4
[illegible]	35.3
[illegible]	42.8

Table 4 presents the comparative death rates in the Hospital of the Rockefeller Institute[9] and in Bellevue Hospital. From this table it is evident that the death rate at Bellevue Hospital for lobar pneumonia (all types) is almost twice that of the Rockefeller Hospital. The reason for this difference is not entirely clear. Probably the most important factor is the difference in type of patient admitted. Other possible factors are incidence of alcoholic patients, character of nursing, amount of examination by students, and frequency of oxygen therapy.

The mortality rate for type I pneumonia in our series varied, of course, with the age of the patients. In children under 12 years of age it was 3.3 per cent; the figures rose with each decade until in patients over 50 it was 46.2 per cent.

The death rate for type I pneumonia was greatly affected by the presence of pneumococcus bacteremia. For example, in our series there were 412 patients with type I pneumonia who received no serum. Of these, 45 patients who showed a pneumococcus bacteremia had a death rate of 66.7 per cent, while 80 type I patients with negative blood cultures showed a death rate of only 22.5 per cent. In other words, the death rate was three times as high in the septic cases as in the nonseptic cases in this group.

Table 4.—*Comparative Death Rates in Hospital of Rockefeller Institute and in Bellevue*

	Rockefeller Hospital[9]	Bellevue Hospital
Type I	11.6*	28.2†
Type II	28.5	48.9
Type III	43.0	34.1
Group IV	12.8	31.3
Total series	19.5	34.5

* Mostly serum treated cases.
† None received serum.

The death rate in patients with serious complications was very high. Twenty-nine cases of pneumococcus type I empyema showed a death rate of 51.7 per cent. This figure, however, is a little misleading, owing to the frequent discovery of pus in the pleura of moribund patients admitted late in the disease. Five patients with suppurative pericarditis, two with vegetative endocarditis, and eleven with meningitis all died.

Specific Treatment.—The studies of Neufeld[10] in Germany and of Cole[3] in America (1913) mark the beginning of the modern specific therapy of pneumonia.

In Cole's investigations, horses were highly immunized against type I pneumococci; the serum of these horses was then injected intravenously into patients infected with type I pneumonia. The doses of serum recommended were quite high, 100 cc. intravenously every eight hours until the temperature dropped and the patient showed definite improvement. Cole,[11] in a recent review of his studies on the serum treatment of type I pneumonia, gives a complete description of the work. In Cole's series of 431 cases of type I pneumonia, practically all the patients received type I serum. The death rate for his entire series was 10.2 per cent, but there was no control series for comparison.

EVIDENCE OF VALUE OF TYPE I PNEUMOCOCCUS SERUM

Since the original studies of Cole, Dochez and others[3] on the value of type I antipneumococcus serum, a considerable amount of evidence in favor of the value of type I serum has accumulated from various sources. For convenience, this evidence can be submitted under three headings: (1) experimental; (2) clinical; (3) statistical.

1. *Experimental Evidence.*—The experimental evidence in favor of type I serum is very convincing. In the first place, the serum of a horse immunized against pneumococcus type I contains the same immune bodies (agglutinins, precipitins and protective substance) that are found in the human blood of the pneumonic patient after crisis. Furthermore, when a mouse is given as many as a million fatal doses of pneumococcus culture, its life can be saved by the prompt injection of an adequate amount of type I antipneumococcus serum.

Cecil and Blake found that, in the experimental pnuemococcus type I pneumonia of monkeys, type I serum, in every case, saved the animals that had been injected intratracheally with lethal doses of type I pneumococcus culture. Normal horse serum had no therapeutic effect on the infected monkeys.

Goodner[12] has recently contributed additional evidence of the value of type I serum in experimental pneumococcus infections in rabbits, produced by intracutaneous injection of the organisms. Rabbits that received lethal doses of pneumococcus type I intracutaneously were readily saved by intravenous injections of type I serum.

The experimental evidence, therefore, is decidedly in favor of the therapeutic value of type I serum.

2. *Clinical Evidence.*—Cole[3] first pointed out the striking clinical effect that frequently follows the intravenous injection of type I serum. Within twenty-four hours the temperature, together with the pulse and respiratory rate, often drops from a high point to normal. Toxic symptoms are ameliorated and the patient's whole appearance changes. Perhaps the most significant of all the clinical effects is the prompt disappearance of pneumococci from the blood stream of septic patients.

These observations of Cole have been abundantly confirmed by other investigators. It must be admitted that such a prompt and striking clinical effect is not observed in every case and that the patients most likely to yield satisfactory results are those who receive serum early in the disease.

3. *Statistical Evidence.*—The statistical evidence in favor of type I serum is not so convincing as one would expect from the experimental and clinical evidence in its favor. Cole treated 431 cases of type I pneumonia with type I serum and reported a death rate of only 10.2 per cent. As no control series was studied, however, it is impossible to say what the death rate would have been if no serum had been used.

Locke[8] and, more recently, Wadsworth[7] have published their results on the treatment of type I pneumonia with type I serum, the two investigators obtaining the same death rate (from 17 to 18 per cent). In both series, however, patients who were not given serum showed approximately the same death rate (from 17 to 19 per cent).

INVESTIGATIONS AT BELLEVUE HOSPITAL

In 1920 we initiated our studies on the specific treatment of lobar pneumonia at Bellevue Hospital. At this time, standard type I serum had been in use for seven years. On account of certain practical difficulties, it had not achieved the popularity which it apparently deserved. The serum was beneficial for only one type of pneumonia; not infrequently, it excited sharp reactions, either allergic or thermal in the patient; and, further, the technical difficulties connected with the administration of large intravenous doses of serum militated strongly against the extensive use of the serum in small hospitals and in private practice. Even in many large metropolitan hospitals type I serum had been completely abandoned when the studies on refined antipneumococcus serums at Bellevue Hospital were initiated. The time seemed appropriate for testing the therapeutic effect of various serum derivatives with the hope of ultimately obtaining a refined and concentrated product that would be easy to administer, free from untoward after-effects, and possibly polyvalent in character.

HUNTOON'S ANTIBODY SOLUTION

For two years, our attention was concentrated on Huntoon's antibody solution, a water clear solution of antipneumococcal immune bodies, polyvalent for types I, II and III. This product has a very low nitrogen content, and the amount of horse serum protein is so minute that it cannot be detected by chemical tests.

Huntoon's antibody solution contains a high content of protection against pneumococcus type I, 0.2 cc. usually protecting a mouse against 0.1 cc. of a virulent culture. Its protective power against type II is not so marked, while against type III its potency is even lower, the best lots rarely protecting against more than 0.001 cc. of virulent type III culture. The results of our two years' experience with Huntoon's antibody solution[13] have been published in full. At this time it will suffice to refer only to the results obtained in the treatment of type I pneumonia. The actual figures are shown in table 5. One hundred and seventy-one cases of type I pneumonia admitted to six medical wards were treated with antibody solution and showed a death rate of 14 per cent; 171 control cases admitted to six other medical wards during the same period of time received no specific treatment and showed a death rate of 21.1 per cent. In 56 cases of type I pneumonia admitted within forty-eight hours after onset of the disease, *treatment with the antibody solution yielded* a death rate of only 8.9 per cent, whereas 68 control cases admitted to the control wards within forty-eight hours of onset showed a death rate of 23.5 per cent, almost three times that for the treated cases.

Huntoon's antibody solution gave very good clinical results and did away with one of the disadvantages of type I serum; it was never followed by anaphylactic reactions or serum sickness. It, however, possessed no more potency than standard type I serum, and large doses of from 50 to 100 cc. were necessary for satisfactory results. When injected intravenously, the antibody solution produced chills much more frequently than type I serum. Indeed, during the early days of our work with this product, almost every intravenous injection of the solution was followed by a sharp chill and rise of temperature. These thermal reactions were sometimes quite severe, and in three cases the intravenous injection of antibody solution appeared to be the immediate cause of death.

Summarizing, Huntoon's antibody solution was free from horse protein but was no more concentrated than the original type I serum. It yielded very good clinical and statistical results in type I pneumonia, but the injections were often followed by severe thermal reactions.

Table 5.—*Comparison of Mortality Rates in Cases Treated with Huntoon's Antibody Solution and Control Cases**

	Treated			Control		
Year	Cases	Deaths	Mortality, per Cent	Cases	Deaths	Mortality, per Cent
1920-1921	87	14	16.1	79	18	22.8

Total......	171	24	14.0	171	36	21.1

* Patients who died within twenty-four hours of admission are not included.

FELTON'S CONCENTRATED SERUM

From 1924 to 1929, alternate cases of pneumococcus type I pneumonia have been treated in Bellevue Hospital with Felton's concentrated antipneumococcus serum.

Felton's antipneumococcus serum is prepared as follows:

> Twenty per cent anhydrous sodium sulphate is added to standard antipneumococcus serum and allowed to stand in an incubator at 37 C. from one to two hours until a precipitate forms. After filtration the precipitate is dialized in running water from five to seven days, viscous membranes being used for the dialysis. The content of the sac is then adjusted to a p_H of from 4.6 to 4.8, at which point a second precipitate forms. This precipitate is removed and the clear supernatant fluid containing immune bodies and some globulin and albumin is adjusted to a p_H of 6.8 and diluted four or five times with cold distilled water. A white precipitate is thrown down containing practically all the protective substance in the original serum. This precipitin dissolves readily in sodium chloride, is high in protective power, and is practically free from chill-producing substances.[14]

The concentration of Felton's serum varies somewhat with different lots; this inequality, however, is readily overcome by pooling the serums from several horses. The actual ratio of its potency to unconcentrated serum has been difficult to determine for the reason that laboratories have employed different methods of standardization. Felton[15] has recently published an article on the concentration of antipneumococcus serum in which he presents comparisons of the common immunologic reactions of unconcentrated serum with those of concentrated serum. The figures are so impressive that the table is reproduced in full (table 6).

Table 6.—*Comparison of the Common Immunologic Reactions of Pneumococcus Serum and Its Concentrate (Felton)*[15]

	Type I Serum	Type I Concentrate
Precipitins..............................	25-50*	100-900
Agglutinins..	10	100
Complement fixation....................	10	100
Opsonins..................................	40	300
Bactericidal action †....................	10^4	2×10^5
Protection................................	500	7,000
Neutralization............................	50	500

* Numbers indicate highest dilutions giving positive reactions.
† Numbers indicate actual number of bacteria killed.

In this experiment the concentrate was prepared from a certain lot of standard serum and then compared with the original serum in respect to its content of immune bodies. From the results shown in the table, there can be no doubt that the concentrate represents a real concentration of all the known antibodies of antipneumococcus serum. In this particular experiment the immune bodies in the concentrate averaged about ten times the potency of those in the original serum.

Two methods have been employed for testing the potency of antipneumococcus serum. In the older method, recommended by Cole and adopted by the United States Hygienic Laboratory, mice are injected with a constant dose of serum and a varying amount of pneumococcus culture. In Felton's method, the mice receive a constant amount of culture and varying dilutions of serum. The Hygienic Laboratory test requires the survival of 50 per cent of the mice injected simultaneously with 0.2 cc. of serum and 0.1 cc. of an eighteen-hour broth culture of pneumococcus of such virulence that 0.00000001 cc. causes death. The "unit of protection" that Felton employs is that amount of serum which will protect mice against one million lethal doses of virulent pneumococci. According to Felton's "unit" method, a wide variation in potency, ranging from 100 to 2,000 units per cubic centimeter can be demonstrated in serums that have already passed the Hygienic Laboratory standard. In other words, the Hygienic Laboratory test is one that sets 'a minimum standard of potency but does not measure the extent by which the serum may exceed the standard in protective value.

Table 7.—*Mouse Protection Test on Antipneumococcus Serums (Hygienic Laboratory Method)*

Amount of Serum	Gov. Standard No. P. 8	N. Y. State No. 406	Felton's Conc. No. 62
0.2 cc. undiluted..............	S*	S*	D*
0.2 cc. 1:5....................	D	S	S
0.2 cc. 1:10...................	D	S	S
0.2 cc. 1:20...................	D	D	S
0.2 cc. 1:40...................	—	D	S
0.2 cc. 1:80...................	—	—	S

* One-tenth cubic centimeter virulent broth culture in every case. S signifies that two out of three mice inoculated survived, and D, that two out of three died.

In Cole's recent article on the serum treatment of type I pneumonia, he questions the accuracy of Felton's method of standardization and contends that the only reliable method of testing potency is to subject the serum to the most rigorous test possible, namely, that

---

[14] Felton, L. D.: *Concentration of Pneumococcus Antibody*, J. Infect. Dis. **43**: 543-553 (Dec.) 1928.

[15] Felton, L. D.: The Concentration of Antipneumococcus Serum, J. A. M. A. **94**: 1893-1896 (June 14) 1930.

0.1 cc. or 0.2 cc. of the serum shall protect a mouse against 0.1 cc. of a culture of the highest virulence. He suggests that the simplest and most satisfactory way to test concentrated serum would be to make various dilutions of it and test them in the same manner that the whole serum is tested. We have actually carried out such a test and the results are shown in Table 7.

Various dilutions of government standard serum, New York State serum, and Felton's concentrated serum were tested for protective power in mice, each mouse receiving 0.2 cc. of serum and 0.1 cc. of virulent broth culture. When tested by this method the concentrated serum was found to have protective power in much higher dilutions than the unconcentrated preparations. With Felton's serum the mice survived at a dilution of 1:80. With the New York State serum a dilution of 1:10 was the highest to protect mice, and with the government standard serum only the undiluted preparation gave protection. The failure of the undiluted concentrated serum to protect mice is explained on the basis of the well known "zone phenomenon," which so frequently occurs in immunologic reactions.

In Goodner's interesting study of the therapeutic value of various antipneumococcic serums in experimental pneumococcus infection of rabbits, he found that the minimal effective dose was much smaller for Felton's serum than for unconcentrated preparations. Table 8 is part of one of Goodner's [12] protocols and is reproduced here because it shows so clearly the relative therapeutic value of concentrated and unconcentrated serums. The minimal effective dose of Felton's serum (0.2 cc.) was approximately one fifteenth of the minimal effective dose of either of the two unconcentrated preparations. The difference in agglutinin titer was even more marked.

Table 8.—*Comparison of Agglutinin and Rabbit Therapeutic Value of Unconcentrated and Concentrated Serums (Goodner)*

Serum Number	Rabbit Therapeutic Value (Minimal Effective Dose of Serum)	Agglutinin Titer
1. Antipneumococcic serum (horse). Hygienic Laboratory Control P 7	3.0	80
2. Antipneumococcic serum (horse). Massachusetts Antitoxin and Vaccine Laboratory, Lot P 315	3.5	40
3. Concentrated pneumococcus antibodies (Felton). Type I, Lot 56	0.2	640

At the outset of our work we tested the therapeutic value of Felton's serum on monkeys experimentally infected with pneumococcus type I pneumonia. Four monkeys were given lethal doses of pneumococcus type I intratracheally and all four animals promptly developed pneumonia and pneumococcus bacteremia. Twenty-four hours after infection, three of the monkeys each received several intravenous injections (from 5 to 10 cc.) of concentrated serum. The three treated monkeys showed almost immediate signs of improvement, and pneumococci disappeared from the blood stream. The fourth monkey did not receive any serum and died on the third day with a heavy pneumococcal septicemia.

In our investigations with Felton's serum the alternate case method was used; that is, every patient diagnosed as having lobar pneumonia was given a number; the patients with even numbers received the serum—those with odd numbers served as controls. The method of administering the concentrated serum has been described in detail in a previous article.[16] After a preliminary test for sensitiveness to horse serum, 5 cc. of concentrated serum was slowly injected intravenously. From one to two hours later, from 10 to 20 cc. was given intravenously, the dose depending on the potency of the lot and the severity of the case. In general, we have tried to administer from 100,000 to 200,000 units (from 40 to 100 cc.) during the first twenty-four hours of treatment. It is our present conviction that in most cases serum treatment should be completed in forty-eight hours; that is, if results are to be obtained at all, they will usually be obtained within that time.

Table 9.—*Comparison of Mortality Rates in Cases Treated with Felton's Concentrated Serum and Control Cases* *

	Treated			Control		
Year	Cases	Deaths	Mortality, per Cent	Cases	Deaths	Mortality, per Cent
1924-1925	49	10	20.4	57	15	26.3
1926-1927	68	12	17.7	77	22	28.6
1927-1928	83	19	22.9	67	23	34.3
1928-1929	39	7	18.0	33	13	39.4
Total	239	48	20.1	234	73	31.2

* Patients who died within twenty-four hours of admission are not included.

Clinical Effect.—There is no more striking clinical effect in the whole domain of specific therapy than that which frequently follows the early administration of Felton's serum in type I pneumonia. The temperature drops rapidly, very much as in a natural crisis, and all signs of toxemia frequently disappear within twenty-four hours after the initiation of treatment.

The effect of concentrated serum on pneumococcal septicemia is quite as marked as that of unconcentrated serum. Unless the sepsis is extreme (several hundred colonies to 1 cc. of blood), pneumococci disappear from the blood stream after one or two injections of serum.

Effect on the Mortality Rate.—The effect of concentrated serum on the mortality rate of type I pneumonia is indicated by year in table 9. All together, 239 cases of type I pneumonia have been treated with Felton's concentrated serum, with a death rate of 20.1 per cent; 234 alternate controls show a death rate of 31.2 per cent. It is noteworthy that, in the four year period, the death rate of the treated cases has varied from 17.7 to 22.9 per cent, and for the controls from 26.3 to 39.4 per cent. Table 10 is a comparison of mortality rates in cases admitted within seventy-

Table 10.—*Comparison of Mortality Rates in Cases Treated with Felton's Concentrated Serum and Control Cases Admitted Within Seventy-Two Hours of Onset* *

	Treated			Control		
Year	Cases	Deaths	Mortality, per Cent	Cases	Deaths	Mortality, per Cent
1924-1925	26	2	7.7	25	7	28.0
1926-1927	22	0	0.0	27	4	14.8
1927-1928	33	6	18.2	28	9	32.1
1928-1929	22	4	18.2	17	6	35.3
Total	103	12	11.7	97	26	26.8

* Patients who died within twenty-four hours of admission are not included.

[16] Cecil, R. L., and Sutliff, W. D.: The Treatment of Lobar Pneumonia with Concentrated Antipneumococcus Serum, J. A. M. A. **91**: 2035-2042 (Dec. 29) 1928.

two hours of onset of symptoms. Here the contrast between the death rate in treated and control cases is even more striking. One hundred and three cases of type I pneumonia treated with Felton's serum showed a death rate of only 11.7 per cent, while ninety-seven controls had a mortality of 26.8 per cent, two and a half times as high as the treated group.

The favorable results obtained at Bellevue Hospital with Felton's serum, reported by Cecil and Sutliff[16] and in this paper, are fully corroborated by the figures reported for Harlem Hospital in New York by Park, Bullowa and Rosenbluth,[4] who also employed the alternate case method of treatment. One hundred and nine cases of type I pneumonia treated with Felton's serum showed a death rate of 17 per cent, while 105 controls had a mortality of 31 per cent.

Table 11.—*Analysis of the Forty-Eight Fatal Cases in the Series Receiving Felton's Concentrated Serum*

Complicating Factors		Number of Cases
Primary	Secondary	
Moribund	Each of these patients recived less than 20 cc. of serum	9
Pneumococcus meningitis		2
Empyema	1 aged 79 years 1 surgical shock 1 mixed with Streptococcus hemolyticus 1 alcoholism	4
Sepsis with acute arthritis	1 mixed with Friedländer's bacillus 1 alcoholism and auricular fibrillation 1 aged 59 years and late admission	3
Sepsis	5 alcoholism 3 late admission 1 asthma 1 syphilis 1 otitis media	11
Cardiac failure		3
Senility	Ages 62, 65, 76 years	3
Erysipelas	1 pulmonary tuberculosis 1 alcoholism	2
Alcoholism	(2 cases with delirium)	5
Asthma		1
Delirium		2
Late admission		1
None	1 aged 50 years 1 aged 26 years	2
Total		48

Park, Bullowa and Rosenbluth also compared the death rates in treated and untreated septic cases. In twenty-eight septic type I pneumonia patients who received Felton's serum, the death rate was 36 per cent; in twenty-eight control patients with pneumococcus sepsis, the death rate was 71 per cent.

In our experience the administration of concentrated serum has had no appreciable effect on the incidence or death rate of complications.

Analysis of Fatal Cases.—In table 11 are listed the forty-eight patients with type I pneumonia who died in spite of treatment with Felton's serum. Some morbid process other than pneumonia was a factor in nearly every case.

COMMENT

We believe that enough evidence has been submitted in this paper to justify the statement that the various types of pneumonia should be thought of as separate entities. Certainly there is as much difference between type I and type II pneumonia as there is between typhoid and paratyphoid fever. If this is true, the diagnosis is not complete in any case until the type of pneumococcus has been determined. By making use of Sabin's rapid method of typing, the bacteriologic diagnosis can often be determined within a few hours after the clinical diagnosis of pneumonia has been made.

The clinical features of type I pneumonia as stressed in the present study have important diagnostic and prognostic connotations. It is important to appreciate the high incidence of type I pneumonia, its clinical characteristics, and its tendency to frequent complications.

We wish to emphasize once more the variation in the mortality rate for type I pneumonia in different institutions, and for different seasons. It is safe to say that the death rate for type I pneumonia is less than for either type II or type III, but the actual figures vary with the place and the time.

Type I pneumonia is amenable to serum treatment. By the use of serum, a marked reduction in death rate has been reported by many investigators. It is doubtful, however, whether the mortality rate in hospitals will ever be reduced below 10 per cent, as a considerable number of the patients are adults, already afflicted with various systemic and degenerative diseases.

It is difficult to estimate accurately the annual number of type I pneumonias in the United States. However, counting four cases for every death from pneumonia, there are about 480,000 cases of pneumonia in the United States every year. About two thirds of these are of the lobar type and approximately 30 per cent of these, or 96,000 cases, should be type I infections. With a death rate of 25 per cent there would be 24,000 fatalities from type I pneumonia alone. If the figures obtained at Rockefeller, Harlem and Bellevue hospitals are reliable, it seems that from twelve to fifteen thousand lives could be saved annually in the United States by the early and universal administration of type I serum in type I pneumonia.

Type I *unconcentrated* serum has been given a fair trial in private and hospital practice throughout the country but has not been accepted. It has been found unsatisfactory because of its low potency, the frequency of reactions, and the difficulties encountered in its administration.

Felton's concentrated serum has not yet received so extensive a trial; but already its therapeutic value rests on sound experimental and clinical evidence. We cannot agree with Blake[17] or with Cole, who state in recent articles that concentrated serum is still too much in the experimental stage to be advocated for general use. Five years' clinical experience with this product and a marked reduction of the death rate in a large group of cases have convinced us of its therapeutic efficacy.

A comparison of the death rate of patients who received concentrated serum at Bellevue Hospital with that of the patients who received unconcentrated serum at the Hospital of the Rockefeller Insitute is difficult. Cole[11] reports a mortality rate of 10.2 per cent in treated type I patients as compared with 20.1 per cent in our series. It must be borne in mind, however, that the death rate in the untreated group IV cases of his series was only 12.8 per cent, as compared with 31.3 per cent in the Bellevue series; again, in the untreated type II patients, he has reported a death rate of 28.5 per cent as against 48.9 in our series.

---

[17] Blake, F. G.: The Diagnosis and Treatment of Pneumonia, New England J. Med. **202**: 991-995 (May 22) 1930.

With respect to the potency of Felton's serum, we believe that the recent reports of Felton,[15] Goodner[12] and ourselves substantiate the claim that Felton's serum is a concentrated and refined solution of immune bodies approximately ten times as potent as the average unconcentrated serum, the exact ratio depending, of course, on the respective lots of serum used in the comparison. The "unit method" of standardization is an important contribution to the specific therapy of pneumonia, as it affords the physician a fairly accurate gage of the amount of protective substance the patient is receiving.

The incidence of reactions to Felton's serum is much lower than that to unconcentrated preparations. The refined serum in its present form rarely causes thermal reactions. Serum sickness occurred in only 20.6 per cent of a series of 214 patients treated with Felton's serum at Bellevue Hospital. According to Mackenzie and Hanger,[18] 93 per cent of the patients who received unconcentrated serum under their observation developed serum sickness. Furthermore, the serum sickness that occurs after concentrated serum is rarely as severe as that which develops after the use of the unconcentrated preparation.

Finally, the simplified technic used in the administration of the concentrated serum is a great advantage. As doses of from 10 to 20 cc. are adequate, it may be prepared in small vials and readily used when indicated.

SUMMARY AND CONCLUSIONS

1. A series of 3,662 cases of pneumococcus pneumonia in adults and 271 cases in children have been studied clinically and bacteriologically. Of this series 1,161 cases were type I infections and form the basis of this study.

2. Type I pneumonia is considered as a definite clinical entity; it usually runs a typical course, terminates by crisis, and has a high incidence of complications.

3. Type I pneumonia is the most prevalent of all the types, constituting approximately one third of all adult lobar pneumonia treated in Bellevue Hospital. It is quite rare in infants under 3 years of age, but is particularly prevalent in young adults.

4. The mortality rate in 412 patients receiving no serum is 28.2 per cent. For reasons not entirely evident the death rate for type I pneumonia in Bellevue Hospital has shown a steady increase since 1921-1922, when it was 20.0 per cent, to 1928-1929, when it was 42.8 per cent. The death rate for septic type I cases without serum is 66.7 per cent.

5. The evidence in support of the therapeutic value of type I serum is presented from an experimental and clinical standpoint.

6. In a series of 171 cases treated with Huntoon's antibody solution, as compared with an equal number of control cases, the efficacy of the solution is shown by a marked reduction in mortality rate. The disadvantages of this preparation are indicated.

7. Felton's concentrated antipneumococcus serum is described and evidence is presented to show that it is often more than ten times as potent as unconcentrated preparations. A series of 239 cases of type I pneumonia treated with Felton's serum shows a death rate of 20 per cent, as compared with a mortality rate of 31 per cent in a control series of 234 untreated cases. There is a further reduction in death rate to 11.7 per cent in cases treated within seventy-two hours after onset.

8. Type I serum is no longer in the experimental stage. When administered early and in adequate dosage, the clinical results are striking. The present study demonstrates that concentrated serum possesses all the therapeutic value of the unconcentrated preparation. Furthermore, concentrated serum has a much higher potency and a lower content of chill-producing substances and horse serum proteins which make it more easily administered, and less frequently followed by chills, serum reactions and serum sickness.

STUDIES OF THE ETIOLOGY OF THE COMMON COLD *

GERALD S. SHIBLEY, M.D.
KATHERINE C. MILLS
AND
A. R. DOCHEZ, M.D.
NEW YORK

In recent years widespread recognition has come about of the fact that the common cold is not a simple minor infection of the upper respiratory tract which, because of its mild symptomatology, can be conveniently disregarded. The more thorough study of this disease begins to indicate that perhaps it may be the keystone of that complex structure of ills the etiologic agents of which gain entrance to the body by way of the upper respiratory tract. A complete understanding of the pathogenesis of the common cold would not only be of value in solving the nature of this malady itself but would undoubtedly throw important light on the mechanism of all respiratory infection and even perhaps on certain diseases that are not regarded as clearly respiratory in origin.

Information concerning the etiology of the common cold is obviously the sine qua non of the understanding of this infection and of its causal relationship to other disease. Many organisms have at different times been assigned an etiologic rôle and frequently the evidence in favor of one or another agent has been impressive. Many of the organisms described have been comparatively well known and in many instances easy to study bacteriologically. To all students of upper respiratory infections the importance of such organisms has been clear, yet not one of them has maintained its position as the principal initiating agent, but all have sooner or later been assigned a secondary rôle. What, then, is the complex sequence of events in which so many microorganisms seem to participate?

For a number of years we have been studying the problem of the etiology of the common cold. We have sought from the beginning to attain our goal by a process of elimination, realizing, from the beginning, that the final word about the significance of any organism could not be said, at any stage of the investigation, but following the evidence where it seemed to lead in the hope that, in the end, the mechanism of the infection would become clear.

Our first efforts were directed toward displacing the common potential pathogens of the upper respiratory tract such as pneumococci, streptococci, Pfeiffer's bacillus, staphylococci, the gram-negative cocci, and the gram-negative filter-passing bacteria, described first by Olitsky and Gates,[1] from the position of primary importance. In pursuit of this objective a number of normal individuals were studied, and by making serial cultures over periods of several months the basic bacterial flora of their noses and throats was determined. Concurrently detailed observations were made of quantitative and qualitative changes occurring in this flora during the course of colds. From the results of this study we were led to conclude that none of the aerobic organisms are of primary etiologic significance because none appear for the first time or in significantly increased numbers during the early days of the cold. Later they may be present as important secondary invaders. This agrees with the earlier observations of Bloomfield.[2] Furthermore, for essentially the same reasons we came to the conclusion that the filter-passing anaerobes constitute part of the normal flora of the upper respiratory tract and do not have a causative relationship to the common cold.

[18] Mackenzie, G. M., and Hanger, F. M.: Serum Disease and Serum Accidents, J. A. M. A. 94: 260-265 (Jan. 25) 1930.

* From the Department of Medicine of the Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital, New York.

* Read before the Section on Pharmacology and Therapeutics at the Eighty-First Annual Session of the American Medical Association, Detroit, June 27, 1930.

Following these observations an effort was made to test the hypothesis that colds are caused by a filtrable virus, one of those mysterious agents the exact nature of whose biologic activity still remains obscure. Important evidence in favor of this view had already been brought forward by a number of investigators.[3] We decided to use animals for the experiment and in searching about for a suitable animal we discovered that anthropoid apes are supposed to catch colds. We soon found, by inquiring of workers with these animals, that the higher apes readily contract colds from human beings and furthermore that these colds are similar clinically to those observed in man.

A colony of young chimpanzees was assembled and placed under observation. To guard against accidental infection they were kept in specially organized rooms under rigid quarantine whenever experimental procedures were in progress. The animals in the stock room could not be so rigorously protected from contact infection because of insufficient facilities. Very early in our work we learned the truth of the report that anthropoids are susceptible to the human type of upper respiratory infection. When the men handling the animals have had colds, the apes in the stock room have frequently contracted the infection even though the men have always worn gauze masks. Colds of this type spread rapidly from ape to ape and the clinical picture is similar to that observed in human beings. At first there is a small amount of glairy mucus in the nostrils. By the end of the first day the animal usually appears quite sick. Lassitude is fairly striking, the eyes are puffy and drooping, a moderate to profuse nasal discharge of thin mucus runs down over the upper lip, there is definite nasal obstruction which makes it difficult for the animal to take liquid food, and breathing becomes audible. There is occasional sneezing and coughing, the appetite is impaired, and rarely there has been diarrhea. Usually there is no elevation of the temperature. By the second or third day the nasal discharge becomes mucopurulent and the throat at times shows evidence of inflammation. Recovery is usually complete in from a week to ten days. Occasionally bronchitis is a sequel and there has also been a persistence of purulent nasal discharge indicating a paranasal sinusitis.

A continuous study of the bacterial flora of the upper respiratory tract in the chimpanzee has been undertaken. The bacteria of the throat have been discovered to be surprisingly similar in man and in the ape. The usual basic organisms such as nonhemolytic streptococci and gram-negative cocci are identical in incidence. *B. pfeifferi* and *S. hemolyticus* are more frequently present in the ape than in man. As in man, pneumococci are only rarely obtained when blood plates are used as culture mediums. In cultures from the nose the staphylococcus is usually the predominating organism in man and is the same in incidence and numbers in the ape. Diphtheroids that are frequent in the nasal flora of man are lower in percentage incidence in the chimpanzee. Gram-negative filter-passing anaerobes also have been cultivated from nasal washings obtained from apes, but the exact incidence of these organisms has not been determined.

From the foregoing facts we may conclude that chimpanzees are susceptible to the human type of upper respiratory infection; that the clinical manifestations noted when these animals catch colds closely resemble those seen in man under similar conditions, and that the bacterial flora of the nose and throat of chimpanzees is practically identical with that of man.

We are therefore assured of the suitability of chimpanzees for the experimental transmission of the common cold from man to animals. The apes in each experiment were placed in strict quarantine, and a rigorous surgical technic was employed by the workers who came in contact with them. Food, utensils and cages were sterilized as far as this was possible. The animals were kept in quarantine for five or more days before being used to test the efficiency of the isolation and to exclude the possibility of latent respiratory infection. No animal under this type of isolation has contracted other than an experimental cold during the period of study.

At the conclusion of the period of preliminary observation, individuals suffering from suitable types of colds were sought out. Nasal washings from the subjects with colds were obtained by running slightly warmed buffered meat infusion broth into their nostrils and thence out through the mouth. From 10 to 20 cc. of broth was gargled and added to the nasal washing. The material was then passed rapidly through a Berkefeld V filter. The unfiltered washing was cultured aerobically and the filtrate anaerobically on blood plates, blood broth and Smith-Noguchi medium. As a further control, 0.25 cc. of filtrate was injected intracerebrally or intracisternally in rabbits in order to exclude the presence of herpes virus. As soon as possible after filtration of the nasal washing, 1 cc. of filtrate was injected with careful aseptic precautions into each nostril of the quarantined chimpanzees. For each experiment it was customary to collect two nasal washings at intervals of a few hours and to make two separate intranasal inoculations in each experimental animal.

In all, twenty-eight inoculations of chimpanzees have been made with filtered nasal washings from human beings. Of these, twenty were obtained from patients in the acute stage of the common cold and eight from normal individuals at a season of the year when colds were at their lowest incidence. Of the twenty experiments with filtrates from colds, four have been excluded since the inoculations were made in animals recently purchased which had recently suffered from respiratory infection. Of the remaining sixteen animals, seven contracted experimental colds, an incidence of 44 per cent of successful transmissions. The symptomatology of the experimental cold resembled exactly that of the spontaneous cold previously described. The usual incubation period was from thirty-six to forty-eight hours. The onset was characterized by lassitude, loss of appetite and the presence of a mucous nasal discharge. This was quickly followed by nasal obstruction, sneezing, coughing, and sometimes by inflammation of the pharyngeal mucosa. The mucous discharge eventually became mucopurulent and symptoms at times lasted as long as three weeks.

Perhaps the most significant change observed has been the increase of activity on the part of the potential pathogens habitually present in the throat flora. Coincident with the appearance of symptoms, pneumococci, *Streptococcus hemolyticus* and *B. pfeifferi* have developed in greatly increased numbers and have spread over a wide area of the nasopharyngeal mucous membranes. These organisms become at this time conspicuous even in the nose, where they are seldom or never present under normal conditions. The same phenomenon has been observed in the spontaneous colds of apes but has not been observed in human beings.

Control experiments of two types have been performed. Chimpanzees have been inoculated with heated filtrates from colds and in no instance has an experimental cold developed. A somewhat better control has been the inoculation of the animals with filtered nasal washings from normal human beings, obtained at a time when colds were not prevalent. Following the latter inoculations, no symptoms whatever have been observed and no qualitative or quantitative change in the potentially pathogenic nasopharyngeal flora could be determined.

Filtered nasal washings from human beings suffering from colds and from normal individuals have contained gram-negative filter-passing anaerobes in nearly the same proportion of instances. No evidence, however, has been obtained that these organisms have any etiologic significance in the initiation of a cold. A number of positive results have been obtained with filtrates in which these bacteria were absent. Many times experiments have been negative with filtrates from colds which contained large numbers of these anaerobes. Furthermore, inoculation of fresh cultures of these organisms from subjects with colds has always failed to produce respiratory symptoms in the ape. Organisms of this type have been present in the filtered nasal washings of 75 per cent of normal individuals; following the inoculation of this material into apes, no symptoms have resulted.

During the course of this animal experimentation we have observed that the duration of immunity from colds has been from three to four months. During the epidemic of influenza in the early winter of 1929, the chimpanzees in the stock room contracted, from one of the keepers, a type of respiratory infection characterized by pronounced constitutional and respiratory symptoms, which was quite unlike the common cold. This occurred well within the immune period and suggests that this influenzal infection is caused by an etiologic agent different from that of the common cold. Exposure of sound animals to apes suffering from an experimental cold has resulted in a contact cold of similar nature in the exposed animal. On two occasions, experimental colds have been successfully transmitted from chimpanzee to chimpanzee.

As a consequence of the foregoing observations we have considered it advisable to attempt the experimental transmission of the common cold from man to man. For this purpose human volunteers, preferably young adults, were secured. They were placed under rigorous isolation of the type described and under the control of a nurse experienced in the application of surgical aseptic technic. A fore-period of five or more days was instituted and all articles entering the room, including food, whenever possible were sterilized. On entering quarantine the subjects were given a thorough physical examination. A study of the throat flora by daily culture and a mouse inoculation was undertaken. All physically unsuitable individuals and all who harbored possibly dangerous pathogens in their upper respiratory tracts were excluded from this type of experiment.

At the termination of the period of observation and study the selected volunteer was inoculated intranasally in the manner previously described with filtered nasal washings obtained from individuals suffering from the early stages of the common cold. In a number of instances plain sterile broth was injected intranasally to exclude and control any symptoms that might arise from the irritating effect of the broth itself. Irritation arising from this source was found to be negligible. Nine experiments of this type have been completed and in four instances colds have been successfully transmitted, a 44 per cent incidence of positive experiments, which is the same as that obtained in the study with anthropoid apes. Objective signs of upper respiratory infections were considered indispensable for the interpretation of a result as positive. These consisted in injection of the conjunctivae, profuse nasal discharge, mucopurulent postnasal discharge, frank inflammation of the nasopharynx with swelling of the lymph follicles and continuous cough. The common symptoms were stuffiness of the nose, sneezing, sore throat and headache. No fever was observed during the course of the attacks. The duration of the colds was approximately one week. Two of the subjects experienced exacerbation of their colds on being discharged from quarantine, and this was interpreted as signifying the acquisition of secondary infection due to exposure to contacts on release from quarantine. Manifest secondary infection obviously could not take place during the period of isolation and, furthermore, all individuals harboring dangerous pathogens were excluded from the tests, so that one would expect this symptomatology to be less severe than in an individual having many daily contacts and therefore being frequently exposed to secondary infection. Filter-passing anaerobes were present in all the filtered nasal washings used in the studies of human transmission, both the positive and the negative results. The varieties of anaerobes present were the same in the two instances. For the reasons previously stated, these organisms are not believed to possess primary etiologic significance.

CONCLUSIONS

The foregoing experiments lead us to certain definite conclusions. The contagious cold in human beings is caused by an invisible uncultivable, filtrable agent which in all likelihood belongs to the group of so-called submicroscopic viruses. Colds can be transmitted successfully from man to the chimpanzee and from man to man by means of Berkefeld filtrates of nasal washings obtained from individuals suffering from spontaneous colds more especially during the period of rising incidence of infection in the community. These experimental colds resemble in all respects colds spontaneously contracted in the natural environment. In apes, one of the significant effects of infection with the filtrable agent is the stimulation into greatly increased activity of any potential pathogen that may happen to be present in the upper respiratory flora. This we regard as of great importance since it seems to explain the marked secondary activity in the respiratory tract of such organisms as pneumococci, *Streptococcus hemolyticus* and Pfeiffer's bacillus, which lead to the severe sequelae which sometimes follow the common cold and influenza. In fact, the most important significance of viruses of this type seems to lie in their capacity to incite activity on the part of the more dangerous pathogenic organisms that infest the upper respiratory tract.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. SHIBLEY, KATHERINE C. MILLS AND DR. DOCHEZ, AND DRS. CECIL AND PLUMMER

Dr. Ernest E. Irons, Chicago: In 1912 I reported two fatal cases following injection of foreign proteins. One patient had typhoid and one multiple arthritis. The postmortem showed in one case multiple thrombosis, including thrombosis of the renal artery. That the number of fatal cases following this kind of therapy is small does not alter the fact that after all is said and done these patients who have such unfortunate reactions are none the less dead. The work of Drs. Cecil and Plummer is admirable and those who have followed their work from year to year have been tremendously interested in the progress they have made along with others of their colleagues. The figures that they present are striking in that if one considers relative figures the death rate in treated cases is definitely lower. In trying to translate this type of work into what may occur if serum is used generally throughout the country, one has to be a little cautious in drawing conclusions. The mortality in pneumonia varies in different years and in different localities in the same year. So statistics gathered over a period of years must be interpreted with due regard to the component years that go to make up the total numbers. Drs. Cecil and Plummer have made definite progress in the treatment of pneumonia, but I still feel that caution should be exercised in recommending the use of serum for general use all over the country.

Dr. Joseph L. Miller, Chicago: I am interested in this paper of Drs. Cecil and Plummer because it is the first time that they have used anything in pneumonia that I felt convinced was beneficial. I was quite certain that the Huntoon's antibody solution which they used formerly was nonspecific, because the same thing can be done with typhoid vaccine intravenously. Huntoon's antibody solution had no effect whatever even in 1,500 cc. doses given intramuscularly. The immunized chicken serum of Keyes worked fine but it gave chills. He took out the fibrin and it gave no more chills and was no good. Any serum that gives chills raises the question of a nonspecific reaction. I have tried Larson's serum made from immunizing sheep. He showed quite remarkable results. He sent me some to use. He said, "This has been purified." It was purified so that it did not give a chill and it did not give any results. But this work here I think is interesting and convincing. I would be interested to see, though, how this serum would work on a series of type IV cases. I surmise that a definite lowering of mortality will result in a type IV series because I believe that none of these serums are strictly type specific. I wish to call attention to what has been noted so frequently in the past, that no matter what the laboratory tells about therapeutic measures, one must determine what it does to the patient. It is good work and I feel that at last something has become available that can be used at least in type I pneumonias.

Dr. Charles J. Wehr, Bellevue, Ohio: Is the use of stock bacterins to prevent colds useless? Will it be possible to obtain a product to use in preventing colds? Is it advisable to use antipneumococcus serum for typing of the pneumonias and is it available?

Dr. Gerald S. Shibley, New York: The chimpanzee is the animal we are using, a most intelligent and cooperative animal when treated right. The "stock vaccine" prevention of colds, or the whole problem of vaccination against colds, is an open one. It may be recalled by those who have worked with such vaccines that there are a few individuals who were considered benefited and many who were not helped. Perhaps some are entirely skeptical about the value of such vaccines. If one is to accept our finding that certain organisms such as pneumococci, hemolitic streptococci and Pfeiffer's bacillus are factors in the late phases of colds, it is highly probable that vaccines containing these organisms are of value in reducing the secondary manifestations. When large series are studied there is no striking difference between vaccinated and unvaccinated groups. In the last piece of work that was done in England three or four years ago, those who were vaccinated seemed to have more colds than those who were not vaccinated. Many workers have described what they believed to be causative agents of the common cold. Back in the seventies, *Micrococcus catarrhalis* was so named because it was believed that catarrhal fever (the common cold) was caused by that organism. It is now known that this organism is present in throats all the time in large numbers. One organism after another has been accused since of being the causative agent. Every one of the ordinary upper respiratory organisms has been implicated at one time or other. Recently the newspapers have given some publicity to a discovery in Baltimore which proposes that colds are caused by a "new micrococcus." It is certain that we have been able to produce colds with material which is essentially bacteria-free in the sense that it has gone through Berkefeld filters. There is no question about these colds; they do occur and they are produced in this way. Whether this is the only way that one may produce colds is still uncertain. It is highly probable that colds may be caused by other bacteria; and in individuals who are highly susceptible to infection I think the factors of tiredness, weather, cold and so on, all may play a part.

Dr. Russell L. Cecil, New York: There is always danger that an investigator of some therapeutic agent will become too big a booster, and I certainly do not want to take that position with regard to Felton's serum. On the other hand, is there not danger of being overcautious in advising the use of a product of this kind? There are about 24,000 type I pneumonias in the United States every year. That, of course, is a rough estimate and will vary from year to year. If that is the case and if this is an apparently harmless product which will reduce that death rate from one third to two thirds, has not the time come when an effort should be made to make the serum treatment of type I pneumonia as universal as possible? After Felton's serum, serum sickness develops in only 10 or 11 per cent of cases as compared with 90 per cent after the original serum. The newer product rarely excites a chill. Of course, a test must be made for hypersensitiveness, but that is easily done. The method now recommended is to put a drop of horse serum in the patient's eye and watch for reddening of the conjunctival sac. If that does not occur in ten minutes, one is quite safe in going ahead and giving intravenous injection of the serum. We have treated more than 500 cases with Felton's serum without a single fatal accident and similar results have been obtained at the Harlem Hospital. It would seem, therefore, that the time is ripe to introduce this product into general use by the profession. Dr. Wehr asked about the use of the serum when typing is not available. The answer I usually give to that question is that I am disposed to be radical in the pneumonia of young people, as type I pneumonia is so common in young people; about 40 per cent of all the pneumonia in young adults is type I. In elderly patients about two thirds of the pneumonias fall into the type III or type IV group, so it is well to wait until typing has been carried out. The Sabin method of rapid typing seems to be quite accurate; we are using it now in Bellevue in all our cases, checking it by the old method. By the Sabin method it is possible to get a report within three or four hours after the sputum has been collected.

EXTRA-UTERINE PREGNANCY

A STUDY OF ONE HUNDRED AND SIXTY-SEVEN CONSECUTIVE CASES [*]

CHARLES A. BEHNEY, M.D.
PHILADELPHIA

Extra-uterine pregnancy is a fairly common gynecologic disorder, which is sometimes easily recognized. Operations for this condition are notorious for the many diagnostic disappointments that attend them. Schumann, in his monograph on this subject, asserts that even in the hands of expert gynecologists a high percentage of diagnostic errors feature the disorder. He continues with the statement that even when rupture has actually taken place the clinical and physical signs so frequently parallel those of other abdominal lesions that it is difficult to form a clear conception of the condition existing within the peritoneal cavity. Diverse opinions regarding the etiology of ectopic gestation are also familiar to all students of medicine. Because of the striking features of the so-called textbook cases, extra-uterine pregnancy has become one of the most dramatic disorders encountered by the gynecologist and obstetrician. On the other hand, instances are not infrequently observed wherein the clinical course is no more violent than in the average case of pelvic inflammatory disease. In order to clarify the apparently confusing elements of this gynecologic problem, a study of 167 consecutive patients with extra-uterine pregnancy who underwent operation in the Gynecologic Service of the University of Pennsylvania Hospital has been undertaken.

While, on the whole, excellent records were available for this investigation, it was inevitable that occasional histories were incomplete in some details. When operation was performed as soon as possible after admission, preoperative diagnoses and many other observations were not always recorded. Furthermore, many of the more recently adopted laboratory procedures were not available for the earlier cases of this series. In other instances, ambiguous statements required interpretation. Finally, the present conception of tubal abortion was not prevalent when most of these patients came to our service, and these statistics, no doubt, include many cases diagnosed as unruptured tubal pregnancies, which would now be regarded as tubal abortions.

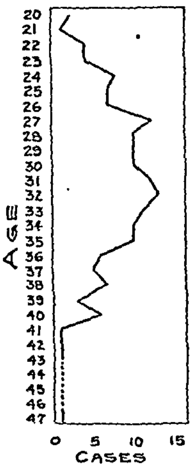

Chart 1.—Age incidence of extra-uterine pregnancy.

The patients varied in age from 20 to 47 years. The greatest number occurred between the ages of 27 and 35 years inclusive. Thirty-one had never before been pregnant. Two had had previous ectopic pregnancies. One hundred and six, or 76 per cent, had previously conceived normally. Two patients had given birth to nine children; two, to ten; one, to eleven; and one, to twelve. The largest number of cases occurred among multiparas, but as the parity increased the incidence decreased.

PREVIOUS INTRA-UTERINE PREGNANCIES

The time of establishment of puberty and the character of menstruation were studied with the idea of determining the influence of genital hypoplasia on the occurrence of ectopic pregnancy. Fourteen years was considered to be the limit for the normal establishment of menstruation.

In endeavoring to discover the part played by previous inflammation of the pelvic organs, we considered, first, the percentage of cases in which the history was in the least degree suggestive of previous pelvic trouble; secondly, the condition of the opposite adnexa as found and recorded at operation. Forty-eight of 131 patients complained of pelvic symptoms or had had previous pelvic operations, including appendectomy, before the occurrence of this disease. In 46 per cent of 123 cases there was some abnormality of other pelvic structures.

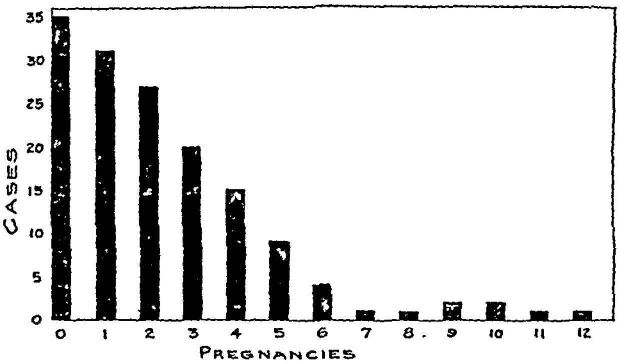

Chart 2.—Previous intra-uterine pregnancies.

Hydrosalpinx	14	24.7
Hematosalpinx	3	5.4
Ovarian cyst	1	1.7
Parovarian cyst	1	1.7
Cystic ovary	2	3.5
Bicornate uterus	1	1.7

One patient had been operated on previously for tuberculous salpingitis, and two had undergone operations for former extra-uterine pregnancies.

Pain was localized in the right lower part of the abdomen fifty-one times; in the left lower part of the abdomen, forty-three times, and was recorded as being bilateral, or generalized abdominal pain in fifty-eight cases. Abortion had been attempted by twelve patients, and syncope was reported positively in 24 per cent of the series. Although irregular bleeding did not occur in eleven patients, seven of these stated that they had observed an increase in the quantity and duration of the menstrual flow. Urinary disturbances were present in 34 per cent of the cases, and nausea occurred in 46.3 per cent of the series. The passage of uterine casts was reliably noted on only three occasions. In most instances, pain had been present from one week to two months before operation. Symptoms of sufficient severity to require immediate hospitalization were present in comparatively few individuals.

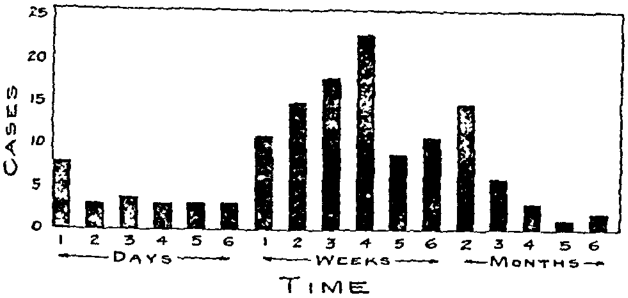

Chart 3.—Time from onset of pain to operation in 143 cases.

Table 3.—*Missed Periods Before Onset of Pain in 127 Cases*

	Cases	Per Cent
No amenorrhea	32	25 3
1 week after missed period	10	8 0
2 weeks after missed period	16	12.6
3 weeks after missed period	7	5.5
4 weeks after missed period	31	24.4
5 weeks after missed period	11	8.6
6 weeks after missed period	4	3 1
7 weeks after missed period	3	2.4
8 weeks after missed period	4	3 1
9 weeks after missed period	0	0 0
10 weeks after missed period	3	2 3
11 weeks after missed period	1	0 8
12 weeks after missed period	3	2.3
15 weeks after missed period	1	0 8
16 weeks after missed period	1	0.8

In the majority of instances, one or more periods had been missed before the occurrence of pain. However, thirty-two patients, or 25 per cent, stated that they did not have amenorrhea.

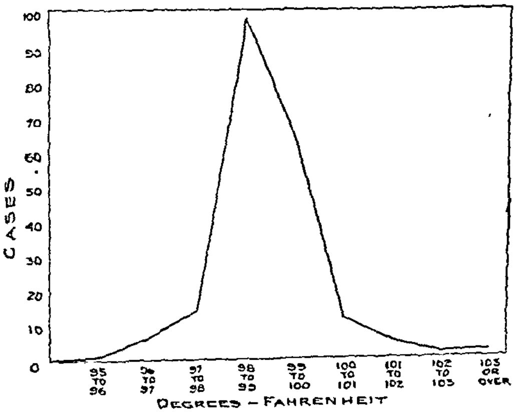

Chart 4.—Temperature on admission.

The temperature and pulse rate usually varied only slightly from normal. On admission, most of the patients had temperatures of between 98 and 100 F., while the pulse rate was commonly found to be between 80 and 100 beats per minute. The average leukocyte count recorded in 108 cases was 11,500, and the average red cell count reported in 63 cases was 3,741,000. In 104 cases, the average hemoglobin estimation was 69 per cent. Sedimentation time was taken in only 10 cases. The most rapid reading was 60 minutes, and the longest time required for sedimentation was 142 minutes, the average time being 68.7 minutes. It should be remembered in this connection that in spite of the great variations in sedimentation times as well as in leukocyte counts, these tests, if considered in relation to symptoms, physical observations and the nurse's records, are invaluable aids in arriving at an understanding of existing conditions.

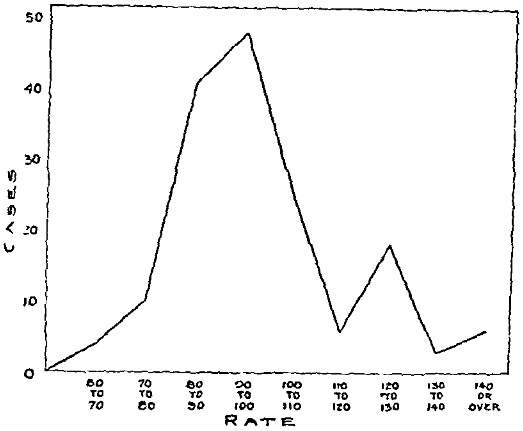

Chart 5.—Pulse on admission.

Our records show that, prior to operation, pelvic masses were found in 85.5 per cent of cases. The cervix was found to be softened in 49 per cent of the patients, and the fundus was enlarged in 57 per cent of the cases. Anteflexion of the uterus occurred in 76 per cent of the series. Cullen's sign, bluish discoloration about the umbilicus, was noted only once.

Table 4.—*Pelvic Masses in 124 Cases*

Site	Cases	Per Cent
Right lower abdomen	46	37.0
Left lower abdomen	36	29.0
Bilateral	7	5.7

* Secondary to old ruptured extra-uterine pregnancy.

† Unsuspected unruptured ectopic pregnancy, associated with these conditions.

Diagnostic errors occurred in 38.7 per cent of cases in which the preoperative diagnosis was recorded.

The occurrence of these lesions was a little greater on the right side, and pregnancy in the ampullar portion of the tube, with rupture, was the most common operative finding. Many of the patients were operated on before the technic of transfusion, which was practiced only five times in this sequence of cases, had attained its present degree of perfection.

One hundred and thirty-two of the incisions healed by first intention. In only 3 per cent of this series did infection occur below the fascial plane.

C infection	2	1.3
Drained	2	1.3

The average preoperative period was 3.4 days, and the mean postoperative time was 22.7 days. The figures, in both instances, have been increased by the very small group of cases in which the diagnosis was obscured by intra-abdominal complicating diseases, which also were responsible for tedious and long drawn out convalescences. Eight postoperative complications, exclusive of wound infections, were encountered. Three of these resulted fatally.

The mortality rate for the entire series was 1.8 per cent. There were three deaths, none of which occurred in typical cases. In no instance was death due to hemorrhage or shock. One patient, with a pyosalpinx on the opposite side and general peritonitis, died two days after operation as the result of the latter complication. The second death occurred eighteen days after operation, in a patient who developed typhoid on the third day after operation. The third patient to die was admitted with intestinal obstruction, complicating an old ruptured extra-uterine pregnancy. She died thirty hours after operation, apparently of cardiac failure. Curiously, none of these deaths took place in the type of case usually regarded as most urgent. Two of the deaths were in patients in whom rupture had taken place in the ampullar portions of the tubes and had become encapsulated. In one case the site of the rupture was not mentioned.

A review of these statistics suggested the practicability of a clinical classification of extra-uterine pregnancy which should provide for three groups. The first of these involves obscure cases of long standing rupture in which encapsulation of the products of conception has taken place. The second includes nonurgent cases in which there is no necessity for immediately instituting treatment. The third group is that showing signs of alarming internal hemorrhage, and in which prompt and speedy operation for the control of bleeding vessels is often required.

OBSCURE CASES

In the group of obscure cases, composed of 6.5 per cent of the series, rupture had apparently occurred from three to six months prior to the admission of the patient to the hospital. Infection of the pelvic hematoma, or adhesions to surrounding viscera, had produced signs and symptoms of other more common abdominal disorders, which in many instances masked characteristic features which otherwise might have led to the recognition of extra-uterine pregnancy. The secondary conditions most frequently distorting the clinical picture were pelvic abscess, pelvic hematocele, tubo-ovarian abscess, and intestinal obstruction. Fortunately there is usually no need, here, for haste in operating, and careful study, particularly of the early history of the disease, will furnish a clue to the real underlying lesion in a large proportion of cases.

URGENT AND NONURGENT CASES

In dividing the remainder of our series into urgent and nonurgent groups, a pulse rate of above 110 beats a minute was accepted as a fair criterion for urgency. Since many women normally exhibit pulse rates of approximately 100 beats a minute, it is obvious that such persons may well show an elevation of 10 or 20 beats a minute, either on account of pain or from excitement, without indicating that their condition is extreme. It therefore is inevitable that there is some degree of overlapping within the groups so selected. Nevertheless, by careful computation of the most typical features of each group, differential criteria can be established.

Table 9.—*Postoperative Complications Excluding Wound Infections*

Complications	Number	Deaths
Obstruction	3	1
Abscess lesser peritoneal cavity	1	1

Pericarditis	1	0
Pleuritis	1	0
Abscess of anterior abdominal wall	1	0

Table 10.—*Comparison of Nonurgent and Urgent Groups*

	Nonurgent, Per Cent	Urgent, Per Cent
Previously pregnant	71.0	76.0
First pregnancy	29.0	24.0
History of previous pelvic disease	40.6	43.3
Periods delayed or irregular	33.3	39.1
Nausea present	46.0	45.7
Opposite side diseased	44.6	51.4
Uterus anteflexed	67.2	64.3
Operated on admission	4.7	45.0
Correct preoperative diagnosis	50.0	93.3
Syncope present	11.5	46.4
Average age	29.4 years	31.8 years
Average preoperative hospital days	3.4	1 4
Mortality	0.0	0.0
Number of cases	116	29

In the urgent group, the percentage of unruptured pregnancies is extremely low and represents patients who, while their condition is not grave, because of individual deviations from the normal cannot be distinguished from those requiring emergency treatment. The remainder in this category are patients in whom rupture had occurred. The nonurgent group, which comprises 74.8 per cent of 155 cases in the entire series susceptible of this classification, contains practically all of the patients with unruptured gestation sacs, and tubal abortions. The fact that a high percentage of ruptured ampullar pregnancies falls within this classification is also in accordance with clinical experience.

Statistics concerning age, previous pregnancies, former inflammation and pelvic changes are so similar in both the urgent and the nonurgent groups that they are of little value in differential diagnosis. However, in the series of urgent cases most patients had missed not more than two periods, while in the nonurgent group there had been as high as five missed periods. Furthermore, in the cases classified as urgent, the duration of pain was in few instances longer than one week before admission to the hospital, while in the nonurgent group the majority of individuals were cognizant of pain for from three weeks to three months. Finally, syncope had occurred in only 11.5 per cent of the nonurgent group, whereas in the category of urgency 46.4 per cent of patients had fainted one or more times. Thus, in addition to the pulse rate, there are three clean cut differentiae for these two types. On one hand, the urgent cases gave a history of a quickly developing critical condition, early in the pregnancy, producing symptoms which developed so rapidly that hospitalization was resorted to in a very short period of time. The clinical picture was so striking that 45 per cent of these patients were operated upon on admission. This is the group which presents the classic picture of extra-uterine pregnancy and which in this series was correctly diagnosed in 93.3 per cent of instances. The average preoperative time was only 1.4 days. On the other hand, many patients in the nonurgent group had been pregnant several months before entering the hospital. Moreover, symptoms had been present for a relatively long period of time before hospitalization became necessary. The average preoperative period in this nonurgent group was 3.4 days, only 4.7 per cent being operated upon on admission. Correct preoperative diagnosis was reported in only 50 per cent of this group. In many of these patients, extra-uterine pregnancy was mistaken for small ovarian cysts, or pelvic inflammatory disease, or was unsuspectedly discovered in the course of an operation for some other pelvic condition as, for example, myoma.

Table 11.—*Frequency of Various Lesions*

Diagnoses	Nonurgent Number	Nonurgent Per Cent	Urgent Number	Urgent Per Cent
Unruptured ampullar	27	95.0	1	5.0
Ruptured ampullar	55	83.5	11	16.5
Tubal abortion	14	83.0	3	17.0

Unruptured tubo-ovarian	1	100 0	0	0.0
Ruptured tubo-ovarian	1	100.0	0	0.0
Pregnant horn bicornate uterus	1	100.0	0	0.0

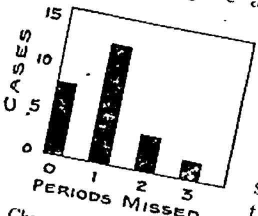

Chart 6.—Urgent group, periods missed on admission.

Ectopic gestation is seen as often in women who have had normal intra-uterine pregnancies as in those who have never been pregnant. Previous pelvic disease, while present more frequently in this series than in an unselected group of women, scarcely occurs with sufficient regularity to be regarded as the sole etiologic factor in a great number of instances. It is quite plausible that pregnancy in tubal diverticula, while reported only once in this investigation, may have sometimes been overlooked. The association of this condition with tubal gestation was not recognized until long after the earlier cases had passed through the clinic. Speedy operations, distortion of specimens by fixing solutions, as well as by the pregnancy itself, and the destruction of the involved portions of the tube by its rupture, make it probable that some diverticula escaped detection. If the occurrence of undifferentiated müllerian tissue lining the tube were to be considered as the cause of pregnancy developing in this situation, it would be remarkable that in 70 per cent of women so deformed the fertilized ova on previous occasions should have successfully traversed the portion of the genital tract so affected and have developed inside the uterus. The common occurrence of anteflexion of the uterus, scant, irregular menses, and late establishment of puberty suggest hypoplasia of the internal genitalia as a factor in some cases. While the etiology of extra-uterine pregnancy cannot be attributed exclusively to any of these causes, it appears reasonable that some condition susceptible of being produced by any one or a combination of these abnormalities may be responsible for its occurrence.

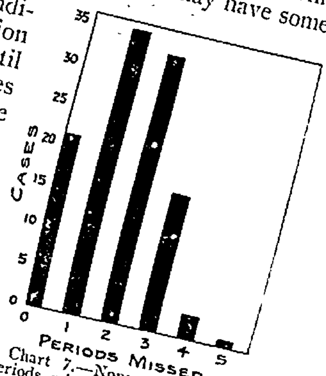

Chart 7.—Nonurgent group: periods missed on admission in 110 cases.

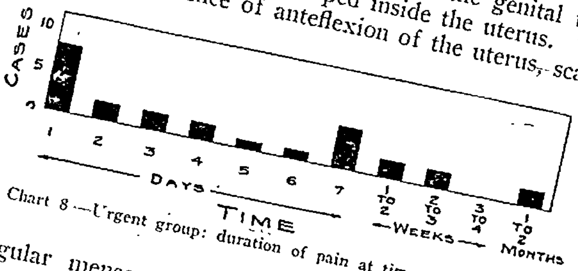

Chart 8.—Urgent group: duration of pain at time of admission.

Extra-uterine pregnancy can occur at any time during the child-bearing period of a woman's life. However, we encountered it most frequently between the ages of 27 and 35 years, inclusive.

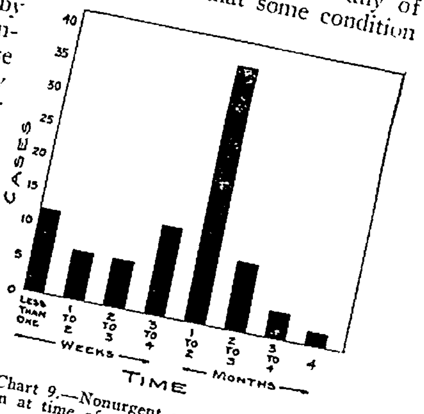

Chart 9.—Nonurgent group: duration of pain at time of admission.

From the standpoint of case history, the salient diagnostic features are a variable period of amenorrhea; recurrent pain consistently situated on either side of the lower part of the abdomen; and scant, irregular bleeding. Moderate decrease in sedimentation time, a mild leukocytosis, and symptoms characteristic of pregnancy are confirmatory observations. Nausea and urinary disturbances are frequently observed. Objectively, there occur discoloration of the cervix, slight enlargement and softening of the fundus, and the presence in the pelvis of an exquisitely tender mass, either boggy or discrete and gradually growing. These are the only signs that were found in this series with sufficient regularity to warrant being accepted as specific diagnostic aids, and on these depends the recognition of extra-uterine pregnancy.

SUMMARY AND CONCLUSIONS

1. The series of 167 cases of extra-uterine pregnancy which has been studied shows that the average case does not conform to the typical picture of the disease.
2. Ectopic gestation may occur at any time within the child-bearing period but is seen most frequently between the ages of 27 and 35 years.
3. The high proportion of anteflexed uteri and irregular or delayed menses suggests frequent association of genital hypoplasia.
4. Parity is no guarantee against future ectopic pregnancy, *but the probability of its occurrence is in inverse* proportion to the number of intra-uterine pregnancies.
5. Although in 80.5 per cent of these patients there had been no complaints referable to the pelvis previous to this extra-uterine gestation, in 46.3 per cent of the number there had been some abnormality of the opposite adnexa.
6. Syncope occurred in 24 per cent of the patients, and in most cases pain had been present from one to six weeks before admission to the hospital.
7. The majority of patients were admitted before three periods had been missed.
8. A temperature at admission from normal to 100 F. and a pulse rate ranging from 80 to 100 beats a minute were observed most frequently.
9. Pelvic masses were found in 85.5 per cent of cases, and ruptured ampullar pregnancy was the commonest lesion.
10. The preoperative diagnosis was correct in 61.3 per cent of the sixty-two recorded instances.
11. The average preoperative period was 3.4 hospital days; the average postoperative time was 22.7 hospital days.
12. There was a mortality of 1.8 per cent. No deaths could be attributed to hemorrhage.
13. Classification into obscure, nonurgent and urgent cases is suggested.
14. The etiology probably depends on a variety of factors, either alone or in combination.
15. The *most reliable basis for diagnosis rests on* history of amenorrhea; recurring, consistently localized lower abdominal pain; metrorrhagia; signs of pregnancy, and a typical pelvic mass.

133 South Thirty-Sixth Street.

ABSTRACT OF DISCUSSION

Dr. Paul Titus, Pittsburgh: The chief object of a statistical study should be an effort to develop a clinical point. Dr. Behney has succeeded admirably in this by showing the more important etiologic and symptomatic factors that will help in making early clinical diagnoses of ectopic pregnancy. One helpful point might be added to his that in many of these cases in which elevation of temperature and of pulse rate with leukocytosis occur, the blood sedimentation test is of immeasurable value in helping one to make a differential diagnosis between unruptured or recently ruptured ectopic pregnancy and an acute inflammatory process. The presence of free blood in the peritoneal cavity, of course, accounts for the observations so easily confused with those of an inflammatory process. However, the sedimentation test remains prolonged within normal ranges rather than being shortened, as in an acute inflammation. This test is so consistent that I have come to place a great deal of dependence on it.

Dr. C. Hollister Judd, Detroit: In diagnosis, can any one do better than B. C. Hirst and Howard Kelley, who diagnose correctly about 75 per cent of their cases of rupture? Of the cases in which rupture does not occur, another authority says, "Unless the case is typical a correct diagnosis is a fortunate incident." Hirst's case, quoted by Kelley, illustrates most emphatically this great difficulty. He had in his hands (the abdomen being open for some other pelvic condition) a pregnant tube of four weeks, and it did not show the pregnancy. The patient went home, and a few weeks later she returned to the hospital with a ruptured extra-uterine pregnancy. In my own cases, the predominant etiologic factor has been gonorrhea. However, as the author says, the cause of a large percentage of cases has still to be accounted for. There are many facts and considerable embryologic data to support his views. Hoffman's case of tubal pregnancy caused by a diverticulum of the tube is in the records. Accessory ostia are not rare. Infantile uterus, ovaries and tubes are frequently seen. In Schoenholz's examination of thirty-two tubes, twenty-six showed a mesh or diverticulum formation which he considers paramount etiologically—also congenital. While it is difficult to prove that embryologic abnormalities of the ovum can cause extra-uterine or ectopic pregnancies, still one can reason in that direction and remain quite logical. The frequent twining of the embryo and various abnormalities said to be present in from 25 to 50 per cent of the cases may be due to errors of maturation, fertilization or ovum diseases. Such conditions could, in turn, cause the embryo to be too large to continue its passage through the tube, or to stick in the constricted cornual portion where likely there are no peristaltic waves. In a case of cornual pregnancy in which I operated a few years ago, no other explanation was offered, the pelvic organs being perfectly normal. Perhaps some cervical pregnancies and abdominal pregnancies could be explained in this manner; in other words, it is just as reasonable to blame the ovum as the mother's genital structure. Bamber reports 150 cases of extra-uterine pregnancy, and says they are increasing as the result of abortions and contraceptives. The abortions might damage the mother's organs; likely the contraceptives could damage the spermatozoa without killing them, and so produce imperfect fertilization.

Dr. W. B. Thompson, Los Angeles: I disagree on the point of nonurgency of isthmian ectopic pregnancies. The tissues, which will not allow for expansion of the growing ovum and when blood vessels are sizable, would seem to me to be a poor place to leave a pregnancy for further bleeding to take place. I was interested in the manner in which his statistics were worked out. They were obtained in a university hospital; ours in a large general hospital where interns and attending men frequently failed to record observations sufficiently clearly to make detailed analyses possible. As to symptomatology, pain was present in 86 per cent of sixty-nine cases studied. Of *particular interest was the fact that shoulder* pain was present in 21 per cent of the cases and was so severe at times as to give rise to a diagnosis of gallbladder disease. Fainting and vomiting were encountered the same number of times; namely, in twenty-three, or 36 per cent, of cases. The temperature range was subnormal in twenty-two cases, approximately normal in four, and elevations from 99 to a high of 103.6 F. in the remaining cases, with an average of 98.8 F. The pulse range was from 70 to 80 in two cases, a high of 160, an average of 106.9. The blood picture, which primarily called attention to the value of looking over the cases, averaged 14,000 white cells, a high point of 48,000, a low of 5,100. *The red blood cells* and hemoglobin depended on the amount of blood loss. The treatment has been immediate operation on diagnosis. Sixty of these cases were ruptured. All the patients were operated on as soon as the diagnosis was arrived at, and there were no deaths. Of the nine unruptured ectopic pregnancies, it *is* impossible to say how many were incidental to other operations, because attending men have the habit, sometimes, of putting down their preoperative diagnosis after the operation is over. That there were nine unruptured ectopic pregnancies is a rather high incidence in such an unfortunate occurrence.

Dr. F. F. Lawrence, Columbus, Ohio: Ectopic pregnancy is much more common than it is usually credited with being. It never occurs in a normal tube; there must be a previous pathologic condition, such as destruction of the ciliated epithelium lining the tube, peritubal adhesions, or kinking of the tube, which prevents the normal peristalsis of the tube, which is always toward the uterus, causing the ovum to be blocked or stopped within the tube. The diagnosis of tubal pregnancy should be made before rupture, because the fallacy that women never die from ruptured tubal pregnancy as the result of hemorrhage is one of the worst fallacies. I have seen several such cases. A positive history of previous tubal disease will be elicited in all cases of tubal pregnancy, if carefully sought for. I have never seen a case in which I could not get a clear-cut history of previous tubal disease. Hence, any type of therapy that attempts to save the tube and prevent operation is an error, because it keeps the life of the woman in constant jeopardy with the possibility of ectopic hemorrhage and fatality. The tube is useless already; the epithelium has been destroyed; the lumen has been occluded, or other pathologic change has developed within the tube and about the tube, which makes its future use nil. It is not frequent for tubal pregnancy to occur bilaterally. I have reported twelve such cases. They are not always found unruptured. In three, one tube was ruptured; the other was not ruptured. In two, both tubes were ruptured, and in one of those the woman died from the hemorrhage before operation could be performed. A diagnosis had been made. Premenstrual pain, an ill defined sense of discomfort through the pelvis, sometimes a period of sterility, although that is not necessary as I have had one case occur eight months after a normal delivery, the signs of pregnancy sharply defined, especially in the breast, a hypersensitive cervix, especially a hypersensitive culdesac on the side in which the tubal pregnancy occurs, and the suspicion of tubal pregnancy is pretty well defined. Medical students and interns should be taught to make careful, thorough examinations gently. It is not uncommon to see a man attempt to examine both sides of the pelvis with his right hand or his left hand. It can't be done gently and safely or thoroughly. The right side must be examined with the right finger and the left side with the left finger in the vagina.

Dr. Lilian K. P. Farrar, New York: Any one who sees a large number of tubal pregnancies sees more atypical than typical cases. Dr. Lawrence said that "the tube is always abnormal." I have seen two or three instances, and I know of a number more, in which the pregnancy was due to a large ovum, implantation evidently coming from the ovary on the opposite side of the pelvis and the delay in passing through the tube, with the pregnancy due to the delay. The tube had been removed on the opposite side and the pregnancy passed into a perfectly normal tube where the tubal pregnancy came. I dislike to take out the only tube that a woman has if she has a tubal pregnancy. I think the justification of doing an implantation into the uterus is sufficient from the fact that cases have been reported of normal intra-uterine pregnancy from such implantation. I remember especially Dr. Thomas Watkins having two cases occurring after resection of the tube in which the tubal pregnancy occurred and then the outer half or two thirds was implanted in the uterus. One of the speakers mentioned differential diagnosis, an examiner having the tube in his hand and not being able to make the diagnosis. I know of three instances in which there was a fimbrial pregnancy; the tube was palpated by good examiners and was felt for the length of the tube, and the diagnosis was made of trouble in the ovaries due to an unruptured fimbrial pregnancy. For several years in suspected cases of ectopic pregnancy the daily white count has been followed, and in unruptured tubal pregnancy, especially tubal abortion, there is a leakage of blood into the pelvis, and there is a high count. With leakage in excessive amount the white count would run up to 20, 30 or even 40 or 50 thousand and drop down again within twenty-four or forty-eight hours to a normal count. The count has been of considerable value when there has been a suspected pregnancy and when this fluctuation has been found in connection with the sedimentation test, which, of itself, is of great value.

Dr. William J. Cassidy, Detroit: After barnstorming the sticks for a great many years and seeing the multiplicity of operations in the metropolitan areas and in the small cabins out in the country, and looking back over a long series of cases, I cannot agree with some of my friends regarding tubal conditions. I defy any surgeon at operation to tell from the general appearance of a tube from the outside as to whether it is infected. I think it is bad policy to advocate radical removal to the younger men. This massacre and mutilation of the woman has occurred simply because she has a pair of tubes and ovaries. They were removed whether she had epilepsy or dropsy. Conservative measures should be adopted rather than the advocacy of radicalism. As to diagnosis, I have had three cases lately—two in unmarried women and one in a married woman, who had the so-called typical clinical symptoms of ectopic pregnancy. They were ruptured ovarian follicles and not tubal pregnancies. There can be all the signs and symptoms—acute, sudden abdominal pain with a previous disturbance in the menstrual cycle, blanching, acute abdominal hemorrhage, massive in type, often simulating all the signs of an acute ruptured tube. Given a patient with an acute ruptured tube, with an abdomen full of blood, the appendix should not be taken out unless one wants to add greatly to one's mortality. There never was an appendectomy done yet that was perfectly aseptic. The abdomen is full of blood and it will be scattered, often with a general peritonitis. I have seen that happen in several instances. These patients frequently come into the hospital late. They are moribund. A history cannot always be obtained. I have seen these cases diagnosed ruptured ectopic pregnancy when there was a ruptured diaphragm or ruptured papillary cystadenoma of the ovary. In women of the child-bearing age one cannot tell whether she has a rupture from a papillary cystadenoma of the ovary which is bleeding rather furiously or a tubal rupture. The only thing one can do is to examine one's patients carefully and get a careful history.

Dr. C. M. Echols, Milwaukee: Looking back over thirty years since my medical student days, it seems to me that there has been strikingly little added to our knowledge of ectopic pregnancy. Now and then some distinguished surgeon or gynecologist has come forward with a suggestion growing out of his own experience that has caused an excited discussion. Twenty years ago Hunter Robb advised that in all these fulminating cases of acute hemorrhage from ruptured tubal pregnancy one should wait until the shock had passed before doing any operation. That suggestion caused a great deal of discussion. It was not unanimously accepted and has not been yet. In my part of the country the men in general practice who see these patients first are much abler to make a diagnosis now than they were in former years. They have been trained to look for the condition. In my earlier cases, most of those which Dr. Behney says were not urgent, curettement had been done before they came to me, the physician being under the impression that the patient was suffering from an incomplete abortion. After the curettement the patients stopped bleeding for a day or two and then resumed bleeding and afterward came in for further examination and a correct diagnosis. Hunter Robb's suggestion was not the only radical one. Many years ago a distinguished gynecologist suggested that in all cases of ruptured ectopic pregnancy it might be well to consider removing the opposite tube lest that tube might later become pregnant. In discussion I told him that I had strong personal objection to that procedure, because my own wife had given birth to all five of our children after she had lost a tube from ectopic pregnancy. As to the allegation that every tube is a damaged tube before it becomes pregnant, possibly that is true, but it could be determined only by very careful microscopic study, perhaps in serial sections. I certainly have not been able to discover any gross pathologic changes in my eighty-seven cases, except in three in which there was pregnancy in a rudimentary horn of the uterus.

Dr. B. H. Breakstone, Chicago: Treatment is often delayed because of uncertain diagnosis, especially in extra-uterine pregnancies. I would rather operate on a ruptured tubal pregnancy, not being sure of a diagnosis, than to have a patient die of hemorrhage. In all gynecologic practice, it is wise to believe every woman of child-bearing age to be pregnant unless one can prove otherwise. Whether she is married or single does not make any difference. Almost any sudden death in a young woman of child-bearing age of a vague abdominal trouble is in all probability an untreated and an unsuspected ruptured extra-uterine pregnancy, especially tubal. If a young woman of child-bearing age who has missed a period and complains of some trouble in the lower part of the abdomen, or a young woman who has always been previously healthy, who has missed a period, never before has fainted in her life, and suddenly faints, she should be rushed to the hospital and operated on, because in 99 cases out of 100 that is a ruptured extra-uterine pregnancy. Many women's lives will be saved if this rule is followed.

Dr. Charles A. Behney, Philadelphia: In order to prevent a mistaken impression, may I add that I do not advocate the nonoperative treatment of extra-uterine pregnancy. Certain patients, classified as urgent, require operation as soon as possible. In these there is no diagnostic difficulty. Patients in whom the symptoms are not clear cut do not require immediate operation. In these the diagnosis can generally be made by careful study and the treatment can be deferred with safety until this has been done.

HYSTERECTOMY

CLINICAL INVESTIGATION OF 1,851 CONSECUTIVE OPERATIONS *

WILLIAM D. FULLERTON, M.D.
AND
ROBERT L. FAULKNER, M.D.
CLEVELAND

Hysterectomy has in recent years become an increasingly popular operative procedure. The frequency with which the operation is done today warrants a careful, unprejudiced, clinical investigation of a considerable number of consecutive cases in which the operation has been performed under similar conditions, in order to estimate correctly the true advantages and disadvantages of this surgical resource.

The rapid development of abdominal surgery and the present comparative safety of the operation may lead to some erroneous conclusions unless the precaution of studying the clinical results is frequently taken.

The refinement of the operation of hysterectomy is certainly among the first of those many laudable advances in surgery which now save and prolong life. W. L. Atlee in 1844 successfully removed a uterus containing a fibroid, and John Bellinger in 1846 did the first planned hysterectomy, though his patient died. Burnham, between 1853 and 1857, did several similar operations and Gilman Kimball in 1883 did eleven such operations with five deaths. T. A. Emmet in 1884 used the vesical peritoneum to peritonealize the cervical stump. Mary A. D. Jones in 1888 did the first panhysterectomy. Stimson in 1889 insisted on the ligation of the individual uterine vessels, avoiding the mass ligature, simplifying the operation and rendering it safer. In 1882, Ahlfeld collected reports of sixty-six abdominal hysterectomies with thirteen deaths.

The general mortality of the present day is extremely difficult to estimate. In the first place a sufficiently large series of operations must be reported to be of any value, and such series are often of selected cases from large clinics by the most expert operators. Their results cannot be taken to give an accurate picture of the present status of the operation in the hands of the average operator.

Graves reports a mortality of 0.79 per cent in 754 supravaginal amputations and of 1.5 per cent in 1,399 cases including all conditions; Chapin, 1.7 per cent in 182 cases, two thirds of which were done for inflammatory conditions. Masson at the Mayo Clinic reported 1,643 hysterectomies for fibroids in 1926, with 1.88 per cent mortality, and in 1927 stated that they had done 229 total hysterectomies with 1.3 per cent, and 217 subtotal operations with 1.8 per cent mortality. Clark and Bauer report about a 2 per cent mortality and Essen-Moller 2 per cent in 799 subtotal, and 6.9 per cent in 117 total hysterectomies. Howard A. Kelly and Thomas S. Cullen, in their monumental work on uterine fibroids, reported a 5.5 per cent mortality in 901 hysterectomies, one fifth of which were panhysterectomies; a later series showed less than a 1 per cent mortality.

These figures indicate that in the best hands at the present time hysterectomy should have a mortality of not over 2.5 or 3 per cent in the selected cases, but the mortality alone does not tell the entire story. The morbidity, immediate and late, and the postoperative complications must be carefully considered, and are, unfortunately, rarely discussed.

There is absolutely no question that the removal of the uterus when definitely indicated is of great benefit to the patient, as frequently by no other means can she be returned to a state of lasting health. However, it is not improbable that as the result of enthusiasm and because of the comparative safety of hysterectomy, many uteri are needlessly sacrificed and the patient subjected to a much more drastic operative procedure than necessary, or even advisable, for her future welfare and comfort.

Every patient must be considered a distinct problem in herself and studied individually. What may be the most appropriate treatment for one woman may be distinctly contraindicated for another. The physical condition, age, duration and severity of symptoms and their etiologic factors, the social status and the marital position of each patient must all be carefully considered and such procedures recommended as will most safely, certainly and quickly return her to a condition of comfortable and permanent health.

In general, though not without a marked degree of elasticity, removal of the uterus is indicated for the following conditions:

1. Cancer of the fundus (operable), and in a few very early cases of cancer of the cervix, though usually with this condition equally good or better results are obtained by the use of radium.
2. Pelvic inflammatory conditions in which the uterus is so covered and involved by the inflammatory masses that it is more easily and safely removed than left, and especially when the fundus is, in addition, subinvoluted and the seat of a metritis.
3. Fibroid tumors:
   (a) Producing ill health or discomfort or interfering with occupation or activities.
   (b) More than 15 cm. in diameter, giving pain and producing symptoms of pressure, especially if these are multiple and when myomectomy is inadvisable.
   (c) Rapidly growing and suggesting cancer.
   (d) Associated with excessive bleeding, producing anemia, though usually relieved by roentgen or radium therapy.
   (e) Associated with repeated attacks of pelvic inflammation or adnexal disease that has resisted treatment.
4. When the ovaries are the seat of papillary cysts and in some instances of multilocular cysts, also with a widespread pelvic endometriosis.

---

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-First Annual Session of the American Medical Association, Detroit, June 27, 1930.

5. When the patient is beyond the child-bearing age, the uterus is large and heavy, subinvolution and excessive bleeding are present, and these conditions are associated with such other conditions as to make an abdominal operation conservatively advisable.

6. In prolapsus uteri, especially when the patient is past 40 and there are associated operable conditions.

7. Following cesarean section when the Porro operation is done as a prophylactic precaution.

8. For the purpose of sterilization, especially when combined with therapeutic abortion, after which future free menstruation is detrimental; as in tuberculosis.

The uterus may be excised by any one of three definite operative procedures, the nomenclature of which is commonly confused. As to which means is preferable, there exists at the present time the greatest divergence of opinion, even among those best qualified to speak. Abdominal panhysterectomy designates the removal of the entire uterus, cervix included, by the abdominal route. Abdominal supracervical hysterectomy designates the removal of the fundus of the uterus, or most of it, only the cervix proper, or at least a part of it, being left. Vaginal panhysterectomy refers to removing the entire uterus through the vagina, though occasionally only the fundus may be amputated through this channel, and if so, vaginal supracervical hysterectomy properly describes the operation.

At any of these three operations, part or all of the adnexa may be excised at the same time, and if they are, it should be specifically designated.

All three of these operations have their advocates and each operation has a distinct and most useful place in modern surgery. The type of operation proposed should always be that best fitted to the case and also to the operator. In the hands of a few expert operators, the operative procedure itself makes but little difference. Here especially should careful attention be given to the selection of the operation best fitted to assure the future welfare of the patient. The vaginal operation rarely competes with the abdominal, as the former is usually reserved for women past the menopause, who have a material degree of prolapse and in whom there are no other (or but minor) associated pathologic conditions.

Whether or not the cervix should be removed with the fundus furnishes the subject for a present widespread heated discussion. Much may be said with truth on both sides and we feel that the argument is best settled by the condition of the cervix itself. Certainly in the hands of the majority of operators, panhysterectomy is the more difficult and longer operation. Anything that prolongs the operative time increases the danger of shock and postoperative complications. Operative trauma and accidents are more common, immediate morbidity is greater. Arguments against this operation include shortening and dryness of the vaginal canal, loss of support for the vaginal vault; increased risk of infection, and a number of operative accidents, all of which, however, depend principally on the preoperative preparation of the patient and the operator's skill and experience with this type of operation.

Great pressure is brought to bear in favor of panhysterectomy in that it removes the danger of subsequent development of cancer in the cervical stump. Graves found five cases of cancer developing in the cervical stump after 1,399 supravaginal amputations of the fundus. Essen-Moller states that he has never seen such a case. Hochman found only three such cases after 1,114 operations at the Woman's Hospital in New York, and Tarnier saw no cases after 1,164 operations. Gagey found 25 cases after 729, and Roque 11 after 379 operations. Masson reports 29 cases of carcinoma in the cervical stump seen at the Mayo Clinic in the previous five years, 21 of which occurred at least three years after operation, but there is no telling from how many subtotal hysterectomies these cases followed. Pemberton and Smith found that only 5 out of 3,814 patients who had had a trachelorrhaphy subsequently developed carcinoma. Among 1,408 women whose cervices were cauterized and 740 who had their cervix amputated, none had developed cervical carcinoma. Only 12 out of 669 patients with carcinoma of the cervix had had a trachelorrhaphy, cauterization or amputation.

Clark found carcinoma of the uterus in less than 1 per cent of fibroids and sarcoma in less than 0.25 per cent. Kelly and Cullen found carcinoma of the fundus in 1.7 per cent of their myoma cases. Graves reports myoma and carcinoma associated in 2 per cent, and Essen-Moller, in 29 cases after 1,000 laparotomies for fibroids, found 18 sarcomas (question of diagnosis), 5 carcinomas of the fundus and 2 of the cervix.

The majority of these unfortunate complications occur strikingly soon after operation, which strongly suggests the presence of the lesion at the time of operation. Before operation, careful inspection of every cervix, and biopsy and diagnostic curettage when indicated, will eliminate such diagnostic mistakes. As urged by Cullen for many years every amputated fundus should be opened and carefully examined immediately. When any indication of cancer is present the cervix is also removed. Although it is true that malignant conditions may develop later in the cervical stump, the risk is certainly no greater, than such disease occurring in the cervix of any woman, if as great. The probability of such occurrence is not to be compared with the added danger and risk of the more severe operation; so that, in our opinion, the cervix, unless the seat of an intractable resistant chronic infection, or suggestive of cancer, should be treated conservatively and not removed at operation. Trachelorrhaphy, cauterization, or even low amputation when indicated, will nearly always leave the cervix in a satisfactory condition. It is true that in a few cases a troublesome leukorrhea may persist, but this will almost invariably yield to cautery treatment.

When doing a supracervical hysterectomy, unless the patient has practically reached the menopause, it is our policy, if possible, to leave a very small portion of the lower fundus in order to preserve at least some slight semblance of menstruation, for which the majority of patients seem appreciative. It is our observation that, if this is done, any symptoms of the menopause are greatly reduced in severity.

We urgently advocate leaving normal tubes and ovaries when the uterus is removed, either partially or completely, and feel that menopausal disturbances are deferred and lessened by so doing. Cystic degeneration of the ovaries or other subsequent complications have not seemed to be increased by such conservatism.

TABULATION OF STATISTICS

With these few generalized remarks we will present a fairly comprehensive statistical study of 1,851 consecutive hysterectomies done by our associates and ourselves at the Lakeside Hospital during the past thirteen years. We believe that the results of this analysis may be most concisely presented in a series of tables, with brief comments on the essential features as shown in each table.

In table 1 it will be noted that the 1,851 hysterectomies were so divided that 58 per cent were abdominal panhysterectomies; 33 per cent were supravaginal amputations; and 9 per cent were vaginal operations. Though 30 per cent of all patients operated on were Negroes, 86 per cent of the abdominal panhysterectomies were done on white women; slightly more than half of the supracervical operations were on Negro women and almost a negligible percentage of the vaginal hysterectomies were on the Negro race. These figures are partly explained by the fact that fibroids and pelvic inflammatory conditions are more prevalent in the Negro race, and also by the fact that the majority of these patients were operated on by the resident staff, who, considering the cause for operation, more often chose the simpler procedure. Half of these patients were nulliparas, as compared with only 20 per cent nulliparas who had panhysterectomy. These figures would indicate that marked prolapse was quite a rarity in the Negro race, and certainly suggest that the Negro woman's uterine supporting structures were less affected by the trials of labor.

Table 1.—*Distribution of Cases*

Number	1,078		609		164	
	Pan-hysterectomy		Supravaginal Amputation		Vaginal Hysterectomy	
Per cent of total	58.2		32.9		8.8	
	Number	Per Cent	Number	Per Cent	Number	Per Cent
Race						
White	933	86.5	295	48.5	161	98.1
Negro	145	13.5	314	51.5	3	1.9
Parity						
0	224	20.7	301	49.9	4	2.4
1+	850	79.3	308	50.1	160	97.6

We particularly note that 20 per cent of the panhysterectomies were in nulliparas, and we ask ourselves the question whether in some of these patients a less extensive operation might not have given just as satisfactory results.

Table 2.—*Ages*

	1,078 Pan-hysterectomy		609 Supravaginal Amputation		164 Vaginal Hysterectomy	
Age	Number	Per Cent	Number	Per Cent	Number	Per Cent
10-19 years	2	0.09	1	0.16	0	0
20-29 years	114	10.5	127	20.8	3	1.8
30-39 years	479	44.4	313	51.5	34	20.7
40-49 years	390	36.1	142	23.2	47	78.6
50-59 years	75	6.9	24	3.9	52	31.7
60-69 years	15	1.3	2	0.32	26	15.8
69+ years	3	2.7	0	0	2	1.2
Average age	39.3		35.7		47.5	

A study of the age incidence of these operations, as given in table 2, shows that the maximum number of panhysterectomies and supracervical operations were performed on women between 30 and 39 years of age, 44 and 51 per cent, respectively. As would be expected, the age in the vaginal cases was greater, the maximum number of patients being between 50 and 59 years. The average age of the panhysterectomy patients was 39.3 years; of the supravaginal amputation patients, 35.7 years; and of the patients in the vaginal cases were about 10 years older, 47.5 years.

The five most common symptoms complained of by all these patients are given in table 3. The frequency of the several complaints is quite parallel in the panhysterectomy and supravaginal operations, except that tumor was a complaint in only 14 per cent of the former as compared to 23 per cent of the latter cases and is accounted for by the increased frequency of fibroids. Any evidence of prolapse on the part of the patient was tabulated as tumor, and the prevalence of this is shown by the fact that it was present in 63 per cent of the vaginal cases.

Table 3.—*Five Most Common Symptoms*

	1,078 Pan-hysterectomy		609 Supravaginal Amputation		164 Vaginal Hysterectomy	
Symptoms	Number	Per Cent	Number	Per Cent	Number	Per Cent
[illegible]	757	70.2	413	67.8	69	42.0
[illegible]	406	37.6	204	33.4	32	19.5
Tumor	159	14.7	144	23.6	103	62.8
Leukorrhea	202	18.7	72	11.8	26	15.8
Urinary disturbance	126	11.6	63	10.3	35	21.3

Table 4.—*Association of Perineal Work with Hysterectomy*

	1,078 Pan-hysterectomy		609 Supravaginal Amputation		164 Vaginal Hysterectomy	
Operation	Number	Per Cent	Number	Per Cent	Number	Per Cent
Laparotomy only						
Simple	202	18.7	269	44.1		
Complicated	74	6.8	56	9.1		
Total	276	25.5	325	53.3		
Laparotomy and perineal						
Simple	633	58.7	217	35.6		
Complicated	169	15.6	67	11.0		
Total	802	74.3	284	46.7		
Vaginal hysterectomy						
Simple	...	...	...	....	2	1.2
Combined	...	....	...	....	131	79.8
Complicated	...	....	...	....	31	18.9

In table 4 it is noted whether, with the hysterectomy, perineal work was done at the same time. It will be seen that there was some perineal work in three-fourths of all the panhysterectomies and in not quite half of the supracervical operations. This indicates that most women who have had children needed some type of repair work, as these figures parallel parity in all types of hysterectomy.

Table 5.—*Previous Operations and Duration of Operation*

	1,078 Pan-hysterectomy		609 Supravaginal Amputation		164 Vaginal Hysterectomy	
	Number	Per Cent	Number	Per Cent	Number	Per Cent
Previous operations	176	17.2	69	11.3	13	7.9
Operative conditions						
Simple	113	10.4	84	13.7	4	2.4
Combined	595	55.1	371	60.9	123	75.0
Complicated	370	34.4	154	25.2	37	22.5
Duration of operation, minutes	102.6		105.7		97.3	

Laparotomy and perineal operations, and laparotomy only, are again subdivided as to whether they were simple or relatively complicated, and it will be seen that, when laparotomy alone was done, 18 per cent of the panhysterectomies were classified as simple as compared to 44 per cent in the supracervical amputations. When perineal work was also done, 59 per cent of the panhysterectomies and 35 per cent of the amputations were classified as simple. The complicated operations of both types, with and without perineal work, were approximately the same.

With practically every vaginal hysterectomy plastic repair work was done at the same time, and 19 per cent were classed as more than ordinarily difficult and extensive.

Table 5 shows that 17 per cent of the panhysterectomies, 11 per cent of the amputations, and 8 per cent of the vaginal hysterectomies were performed on patients who had been previously operated on. This indicates a somewhat more radical treatment for those patients who had not been relieved by their former operative procedures.

The tabulation of operative conditions indicated as simple refers to the presence of but a single pathologic change or anatomic defect; combined, when two changes of major importance were present; and complicated when there were more than two such changes. The percentages in each type of hysterectomy do not vary greatly, except that few of the cases treated by vaginal hysterectomy were classified as simple.

The average operative time is remarkably close in all of the three types of hysterectomy. This time is calculated from the induction of anesthesia until the postoperative dressings are completed. It is interesting to learn that there was an average increase of 12.3 minutes in the operative time in the last 800 supracervical operations. This is probably attributable to the fact that several resident surgeons were rather slow operators and showed a preference for the supracervical operation. The time for the other two types of operation remained identical with that for the first thousand cases.

The operative diagnosis, shown in table 6, gives the more common and important observations at operation. The comparative frequency of the several tabulated conditions shows the much greater frequency of lacerated perineums and cervices, subinvolution, prolapse, gallstones and all types of carcinoma and hernia in those patients on whom a panhysterectomy was performed. Myomas were classed as 1, 2 or 3, depending on their size, 1 when up to 5 cm. in diameter, 2 when 5 to 10 cm., and 3 when greater than 10 cm. in diameter. All types of such tumors were more common in supravaginal amputations, as were pelvic inflammatory conditions. The uniformity of perineal lacerations and prolapse, which includes cystocele, in the vaginal hysterectomies is striking.

Table 7 gives operative procedures and shows that coincident with 1,087 panhysterectomies there were 3,147 additional operations; with 609 supracervical hysterectomies 2,197, and in 164 vaginal operations 296 additional operative procedures. In a very large proportion of both these main operations the appendix was removed and one or both tubes were resected. One or both ovaries were removed in almost half the cases, usually only one, as our policy is conservatism in this respect.

As a rule we examined the gallbladder and found that this organ was diseased in 6 per cent of all panhysterectomies and in about 3 per cent of all supracervical cases. Stones were the cause of this trouble in about 85 per cent of such cases. Cholecystectomy and cholecystostomy were used with equal frequency to care for the gallbladder disease, which was but rarely attempted at the time of supracervical hysterectomy but frequently with the panhysterectomy. Five vesicovaginal fistulas were repaired at the time of pan-

hysterectomy, the latter operation sometimes being used to facilitate repair of the fistula.

The more important operative complications run a close parallel in all types of hysterectomy and are clearly set forth in table 8.

The postoperative complications, shown in table 9, are practically 1 per cent higher in the panhysterectomies, namely, 2.8 per cent. The important finding of eighteen fistulas, the result of the operation in the pan type of hysterectomy, as compared to no such deplorable consequences after the supracervical type, is a warning to use the utmost care at operation to prevent such sequelae and is quite sufficient of weighty preoperative consideration. It is to be said that three of these fistulas followed extensive operations for cancer and three others followed operations done for pelvic endometriosis. Proportionately, postoperative hemorrhage is also much more common after the panhysterectomies; this is not surprising, considering the difference in the procedures, but it urges for extreme care in the matter of hemostasis. None of the hemorrhage cases were fatal; none required secondary abdominal operation. Cystitis is also twice as common after the panhysterectomy. This can readily be understood and is attributable to the greater trauma of the vesicle.

The morbidity table (10) presents some interesting information. It will be seen that 29 per cent of the panhysterectomy patients had an absolutely afebrile convalescence as compared to 26 per cent and 21 per cent of the supracervical and vaginal cases, respectively; but 3 per cent more of the supracervical patients had an elevation for one day, which was so transient that we feel it can be ignored. Therefore, 43 per cent of the panhysterectomy, 43 per cent of the supracervical, and 32 per cent of the vaginal hysterectomy patients had afebrile convalescences.

Panhysterectomy	118	27	21	8	13	11	2	2	3	18	15	31	9	18	6	4	2.8
Supravaginal amputation	56	17	8	8	2	0	0	0	0	12	6	8	2	2	2	4	2.0
Vaginal hysterectomy	5	2	4	3	1	2	0	0	1	2	2	12	0	0	0	1	2.1

The postoperation days in the hospital show a two-day advantage for the supracervical patients that are of the same age; the vaginal cases average slightly longer, but this might be expected, in view of the greater age of the patients

The final table, on mortality, table 11, shows that the visiting staff of five operators performed 63 per cent of the panhysterectomies with a mortality of 3.5 per cent; the resident staff of twenty operators, 37 per cent of the cases with a mortality of 5.2 per cent. The visiting staff did only 39 per cent of the supracervical operations with a 5 per cent mortality; the residents did 61 per cent with 4 per cent mortality. Of the vaginal cases, the visiting staff did 80 per cent of the cases, with 3.8 per cent mortality; the residents did 20 per cent with 2.9 per cent mortality. The gross mortality for 1,078 panhysterectomies was 4.1 per cent; for 609 supracervical hysterectomies, 4.4 per cent, and for 164 vaginal hysterectomies, 3.6 per cent.

COMMENT

Personal impressions and opinions gained from the study of these figures and constant association with the service would provide the following comments. The visiting staff, with their greater experience and the character of many of their cases, more often resort to panhysterectomy, employing supracervical amputation usually in only the more serious operative risks. The resident staff with their many pelvic inflammatory and fibroid cases, half of which are in nulliparas, more frequently utilize the supracervical operation. Their average case is a better risk than such operations of the visiting staff, which accounts for the slightly lower mortality in this group. It is a safe prediction that if the members of the resident staff resorted to panhysterectomy as frequently as do the visiting staff, their mortality would be still further increased.

CONCLUSION

The excellent primary and late results with vaginal hysterectomy, used chiefly in cases of marked prolapse, frequently in quite elderly women, are most satisfactory and unquestionably designates this as the preferable operative procedure in such selected cases.

COMMON DUCT STONES [*]

HOWARD M. CLUTE, M.D.
BOSTON

In the Lahey Clinic during the years 1910 to 1926 inclusive, 619 patients with disease of the biliary tract were operated on. In the 619 cases, exploration of the common duct was undertaken 96 times (15.5 per cent), and 52 patients (8.4 per cent) were found to have stones. In the years 1927 to 1929 inclusive, however, with increased interest in common duct stones we increased markedly the percentage of explorations of the common duct. There were in these three years 413 cases in which operations were performed for disease of the biliary tract; 140, or 33.8 per cent, of these patients had explorations of the common duct; 74 of the patients, or 17.9 per cent, were found to have stones in the common duct. These figures indicate that as the percentage of exploration of the common duct rose from 15.5 per cent to 33.8 per cent the percentage of incidence of common duct stones increased from 8.4 per cent to 17.9 per cent. As we have doubled the frequency of exploring the common duct, the incidence for common duct stones has doubled.

It is probable that most common duct stones arise in the gallbladder or the cystic duct and pass from there into the common duct. It is generally accepted that a stasis of bile with or without infection is necessary for the formation of gallstones. This may come either from obstruction of the duct or from infection of the gallbladder wall and a resulting loss of function of the gallbladder. Stones may arise primarily in the bile ducts, although this is of such rare occurrence that only a few cases have been reported in the literature. Judd and Burden [1] report one such possible case and cite other cases reported by Lewisohn, Murchison and others. Even in the few cases that have been reported, there is often a certain doubt as to the primary origin of the stones in the hepatic ducts. Certainly for all practical purposes it may be said that common duct stones originate in the gallbladder or the cystic duct in the vast majority of cases. If the common duct is dilated it is probable that the stones have arisen from an impaction of some little duration in the cystic duct which occluded it before the stone reached the common duct, or they have been present in the common duct for a longer period of time. It is, of course, true that bilirubin calcium stones may form as a soft paste in the common duct in the presence of detritus and infection, but this method of origin of common duct stones is unusual.

It is generally conceded that a true recurrence of stones in the common duct is extremely rare. The case, however, with which stones can be overlooked and left in the common duct after operation is well recognized by all surgeons. In 1923, Dr. W. J. Mayo [2] stated that nearly one third of the autopsies performed on patients dying after the removal of the common duct stones in the Mayo Clinic showed that there were some stones left behind in the common duct. Dr. Edward L. Young,[3] in studying the fatal cases at the Massachusetts General Hospital after operations on the gallbladder, found that stones were still present in the common duct at autopsy in 61.3 per cent. He stated that in many of these cases there was sufficient cause for not searching for the stones and the real proportion of failure to remove stones after operation on the bile duct was 16.4 per cent. In my own experience I know that I have left stones behind in the common duct in spite of a most painful and diligent search for them. In three of the seventy-four cases in the present series, previous exploration of the common duct had been undertaken in our clinic and in each case I believe that a stone was overlooked at the primary operation.

Seventeen previous operations on the biliary tract were performed in this group of patients before the operation for common duct stones. These consisted of cholecystostomy in seven cases, cholecystectomy in six, drainage of acute pancreatitis in two, drainage of subphrenic abscess in one case and exploration of the pancreas for probable cancer in one. It is probable that in some of these primary operations stones were already present in the common duct and were overlooked.

Patients with stones in the common duct generally have a history of long years of indigestion and epigastric distress. In addition there are occasional attacks of mild pain, more severe than the distress and indigestion that are the usual complaints. I have felt that this dyspepsia and distress had generally been related to the presence of infection and of stones in the gallbladder. When the stones occlude the cystic duct or reach the common duct, the patient is seized with a pain of a different and more serious type. The attacks are frequently of intense severity requiring repeated doses of morphine for their relief. The pain has a tendency to stop as suddenly as it began and not infrequently after its disappearance it leaves no residual tenderness in the upper part of the abdomen. In the typical case, jaundice appears soon after the pain. It may be visible for only a short time or it may last for several days before disappearing. Occasionally the jaundice is intense and persists for weeks or even months. The degree of jaundice varies markedly in different patients and in different attacks. If it can be said that any type of jaundice is typical of common duct stones, it would seem that jaundice which appears suddenly following severe abdominal pain and disappears equally rapidly could be termed common duct stone jaundice. Examination of the stools during the period of the attack of pain and shortly after will not infrequently show one or more stools that are clay colored while all other stools are of the normal brown or yellow color. Likewise, an examination of the bilirubin contents of the blood before, during and immediately after an attack of pain will show a definite elevation of the bilirubin for a few hours following the pain, even in the absence of any visible jaundice.

So commonly has jaundice been associated with common duct stones that it was often believed that in the absence of jaundice no stones would be present in the common duct. Thus, Mayo Robson [4] stated that stones occurring in the common duct without jaundice were seen in less than 1 per cent of cases. Jordan and Weir [5] found that 13.2 per cent of their cases of common duct stones had no history of jaundice and no jaundice at the time of operation. Haggard,[6] in reporting his cases of common duct stones, states that 90 per cent showed jaundice at some time in their attacks. In the present group of seventy-four cases of common duct stones, however, there were twenty-nine patients, or 39 per cent, who gave no history of jaundice in their previous attacks of pain and who were not jaundiced at the time of operation. It is furthermore significant that of the 140 patients in whom the common duct was explored at the time of their gallbladder operations there were 72 who had had attacks of pain and jaundice in the past, and yet in one third of these no stones were *found in the common duct. From these facts it is* apparent, first, that as explorations of the common duct increase more and more patients with common duct, stones will be found who have never been jaundiced and, secondly, that patients will repeatedly be found who have been jaundiced and have had attacks of pain who have no common duct stones.

Chills and fever without any appreciable cause on examination are present occasionally with common duct stones. In our experience, however, this has not been a common occurrence. Loss of weight in certain instances is one of the outstanding features of the disease. This is usually associated with a marked loss of appetite and in some cases has been so extreme as to be the leading symptom for which the patient sought relief.

On examination, tenderness in the right upper part of the abdomen is generally present after an acute attack of common duct colic. This is particularly true if the gallbladder is present. When, however, the gallbladder has been removed, common duct stone colic frequently is not followed by localized tenderness. An enlarged, tender liver edge may be present, especially when cholangeitis is present. In some instances pancreatitis occurs with the attacks and may be suspected clinically by the extension of the tenderness across the epigastrium into the left flank over the tail of the pancreas. Rarely, if ever, in our experience has the gallbladder been dilated and palpable when the obstruction to the common duct was due to stones. Such cases, however, have occasionally been reported.[5]

In patients who have had previous operations on the gallbladder, a return of the old attacks of severe pain after a relatively long period of apparent recovery following operation is most suggestive of a common duct stone remaining in the duct. In these patients indigestion and epigastric distress are less prominent than in patients who have not been previously operated on, and they show on examination relatively little local tenderness after the attacks.

The available diagnostic measures are inadequate in cases of common duct stones. Roentgen examination is usually not valuable, as common duct stones rarely can be diagnosed in this way. Bilirubin estimations immediately after and some little time after attacks of severe abdominal pain may be of particular diagnostic value since there is often a temporary rise in the bilirubin immediately after the pain, which is suggestive. Screening of the stools for the discovery of gallstones will occasionally show the presence of stones. Other than these there are no special measures particularly valuable in the diagnosis of common duct stones and one must rely particularly on the consideration of the clinical history and the conditions found on examination.

The decision as to the best time for surgical intervention in cases of gallstones with common duct obstruction is a most important one and one that frequently presents difficulty. Almost always it is safe to delay for a day or two after the onset of the severe pain. This will give an opportunity for careful study of the temperature, the white blood cell count, the bilirubin and the local condition in the upper part of the abdomen. It is undesirable to operate in the presence of an increasing and uncontrolled infection, as shown by a rising temperature, an increasing white blood cell count, an elevated bilirubin and the local signs of infection.

When bilirubin estimations show that the jaundice is increasing, it is unwise to operate. It is preferable to wait, if possible, until the jaundice is stationary or *decreasing before undertaking surgical intervention. In* the presence of chills, fever, pain and increasing jaundice that are indicative of cholangeitis, however, it is generally agreed that the common duct should be drained at once.

During the preoperative period much can be done to improve the patient's general condition and his ability to stand these serious operations. Fluids are forced by mouth, by rectum and by hypodermoclysis. Dextrose is given with these fluids, and also a diet high in carbohydrates. When jaundice is present, the bleeding and coagulation time are brought to normal limits by the intravenous injections of calcium or by the use of blood transfusions. Estimation of the sedimentation rate of the red blood cells and preparation for transfusion when a high sedimentation rate is present is recommended by Linton[7] in some recent studies of bleeding in jaundiced patients. If this simple test can give a true estimate of the tendency to bleed in jaundice, as seems to be the case from this report, it may well replace the unsatisfactory and unreliable tests of coagulation time.

We now explore many more common ducts at operation, 33.8 per cent, than has previously been our habit. The common duct that is dilated and thickened should be opened and explored in every patient, whether or not stones can be palpated and regardless of any history of jaundice. Exploration of the common duct is indicated in all patients who have had attacks of jaundice with pain whether or not the duct is enlarged. In all cases in which there is much thickening in the head of the pancreas it is preferable that the common duct be opened, irrigated and explored. In any case in which there is any question of common duct stone, irrigation is desirable and, if any detritus is obtained, thorough exploration can then be undertaken.

Certain complications may occur after operations on the common duct which are in some measure peculiar to the operation. Thus, in eight of our cases there were attacks of pain and jaundice coming on soon after operation. In two of these patients we have never been able to discover any cause and they have now gone for long periods with no further trouble. In three of the patients, however, the attacks of pain persisted and were followed by mild jaundice. In each of these patients the diagnosis of a recurrent stone in the common duct was made and in each a stone was removed by further operation. In one patient the postoperative pain and jaundice was found to be due to a stricture of the common duct. We are unable to explain the origin of this stricture which followed a simple cholecystectomy and drainage of the common duct. The stricture at the second operation was found fully an inch below the point of incision of the common duct for the T tube drain. A successful plastic operation was done in this patient at the second operation. In one patient in whom postoperative pain, fever and jaundice occurred we were able to make a diagnosis of syphilis of the liver. This case was most instructive to us and may well be briefly reported.

---

[7] Linton, R. G.: The Sedimentation Rate of Blood in Jaundice, Ann. Surg. **91**: 694 (May) 1930.

A woman, aged 40, had attacks of typical gallstone colic associated with mild jaundice and followed by local tenderness in the right upper quadrant. Nothing could be felt in the abdomen because of her marked obesity. The Wassermann reaction was positive. The gallbladder failed to fill on repeated intravenous injections of gallbladder dye. A diagnosis of cholecystitis with stone and probable common duct obstruction was made and operation was undertaken. At operation a typical gummatous liver was discovered with a thick-walled indurated gallbladder containing no stones. The common duct was markedly dilated and thick-walled. It was opened and its mucous membrane was found to be edematous, raised and thickened so that it resembled granulation tissue. Thick, black bile was removed from it but no stones could be discovered. The common duct was drained and the abdomen closed in layers. The postoperative course was for a time satisfactory but, after eight days, daily fever with increasing jaundice occurred and marked pain was present in the upper part of the abdomen. Mild antisyphilitic treatment had been given soon after operation, but it was necessary to increase the treatment markedly before improvement occurred. With large amounts of mercury and potassium iodide the temperature finally came to normal and remained there, and the pain and jaundice disappeared.

The confusion of common duct stones and syphilis of the liver and the possible involvement of the bile duct by this infectious process was to us a unique experience and one which we feel may well bear consideration in order that it may be avoided by other surgeons. We now believe that in the presence of a positive Wassermann reaction antisyphilitic treatment with, of course, the most careful avoidance of arsphenamine, should be given every patient in whom gallstones are suspected but not proved, unless the patient's surgical condition is so serious that an emergency operation is obviously indicated.

Operations on Biliary Tract in 1927, 1928 and 1929

Operations	Number	Deaths	Operative Mortality, Per Cent
Common duct stones present	74	5	6.7
Common duct stones not present.	339	10	2.9
Total biliary tract operations....	413	15	3.7

It is generally recognized that the presence of stones in the common duct increases materially the seriousness of gallstone disease. That this is true is readily shown by the marked increase in the operative mortality in cases of common duct stone over those in which there are no calculi in the biliary ducts. Thus, as is shown in the accompanying table, there were five deaths in the seventy-four cases of common duct stone, an operative mortality of 6.7 per cent. In 339 patients in whom there were no common duct stones there were 10 deaths, an operative mortality of 2.9 per cent, and it is to be noted that in these 339 patients the common duct was carefully explored 66 times with no mortality.

In reviewing the five deaths that we have had in these seventy-four cases we are impressed by one or two outstanding facts. In each of the five patients, numerous stones were present in the gallbladder as well as in the common duct and each of the patients had had repeated attacks of disease of the biliary tract over several years. Each of the five patients was either jaundiced at the time of operation or had been jaundiced repeatedly in the past. The dangerous time in the postoperative course of each patient was from seven days onward, one patient, aged 77, dying seven days postoperatively and the others dying nine, ten, ten and twenty-one days postoperatively. In each of the five fatal cases, we removed the gallbladder, removed stones from the common duct and drained the common duct. The causes of death were liver and kidney failure, hemorrhage, pancreatitis and retroperitoneal phlegmon.

The fact that stones had been present in the gallbladder and probably in the common duct in all these patients for several years before they came to operation cannot be overlooked, particularly when one considers the number of patients who are told that as long as their gallstones are causing them no symptoms they need not have anything done about them. Silent gallstones, are, however, potentially dangerous and when the patient's condition permits should be removed as soon as they are diagnosed. These fatalities represent the results of watching gallstones until they caused sufficient symptoms to demand active surgical treatment. The most serious difficulties in our experience with the common duct have arisen from the seventh to the fifteenth day after operation and have been related to delayed hemorrhage and the late depression of liver and kidney function that occurred. In certain cases of long standing biliary obstruction with jaundice we have had fatal bleeding which has persisted in spite of repeated blood transfusions, calcium administration and the giving of bile by mouth.

The combination of cholecystectomy with removal of stones and drainage of the common duct is too extensive a procedure for seriously handicapped patients. A division of the operation into two stages has been urged in the past by numerous authors but has not had general acceptance. When it is considered, however, that hemorrhage plays a large part in the deaths in common duct surgery and that liver damage and liver failure are always present in these fatalities, it must at once be obvious that reduction of the trauma to the liver substance, diminution by some few minutes of the operating time and avoidance of the added shock and the added bleeding from removal of the gallbladder can be advantageous only in patients who are poor risks. We have recently operated on several patients for obstruction of the common duct without removing the gallbladder. The patients have done well and we are convinced that a conservative procedure of this type will frequently be life-saving in final results.

The reduction of mortality from common duct stones can be accomplished, first, by the early removal of gallstones in every patient in whom they can be diagnosed; certainly, any patient known to have gallstones who has an attack of colic with jaundice should lose no time in having the necessary operation performed; secondly, by the greatest care and attention to details of preoperative preparation with fluid, dextrose, calcium and transfusion and to similar measures postoperatively; and, finally, by the division of the operation into two parts in long standing biliary obstruction, a factor of great importance in lowering the high mortality. The removal of common duct stones with or without removal of stones from the gallbladder as a first stage and cholecystectomy at a later date must often become the procedure of choice in poor risk patients having common duct obstruction from stones.

605 Commonwealth Avenue.

ABSTRACT OF DISCUSSION

Dr. Bruce C. Lockwood, Detroit: Good results from gallbladder surgery, according to most statistical studies, are obtained in from 70 to 75 per cent of cases. The point to which Dr. Clute calls attention especially is that stones are often missed by the surgeon when they are lodged in the common duct, and that a more thorough search should always be made at the time of operation. I think he will agree that it is often difficult to find them, and, when found or suspected, they are hard to remove. I refer especially to those stones which slip up the hepatic duct toward the liver, and those which become caught or embedded in or near the ampulla of Vater. I have in mind several cases in which the surgeon failed to find such stones which were subsequently shown to be present, and also several patients in whom the stone was found embedded in the ampulla region, but the operation of removal proved so formidable that the patients died after operation. Other causes of poor operative results are adhesions between the duodenum and the operation site, stricture of the common duct, pancreatitis, hepatitis, including syphilis, and other medical conditions. Medical treatment of these biliary tract cases should always be carried on postoperatively, and when patients cannot be or refuse to be operated on. Such treatment is based on known physiologic facts, involving procedures that keep the bile thin and of low viscosity, increase its flow from the liver and its frequent periodic dumping from the gallbladder, lessen its content of cholesterol and increase its content of bile salts, thereby keeping cholesterol in solution. Such medical treatment should also include removal of focal infections, correction of metabolic abnormalities, and the correction of any stomach or intestinal conditions that are found in the individual case. Time does not permit a discussion of the details of medical treatment. I am convinced that the results obtained warrant greater consideration than usually given to the medical management of diseases of the biliary tract, and that such should be used in conjunction with surgery for best results.

Dr. Frederick A. Coller, Ann Arbor, Mich.: One of the outstanding features of the diagnosis of abdominal diseases in the past few years has been the increasing frequency with which diseases of the gallbladder have been recognized. Two facts brought out were amazing to me: First, the large number of cases in which stones were present in the common duct entirely unsuspected. It was thought that the classic picture of common duct stone was a fairly accurate one, but obviously it is not so. Second, the comparatively large number of cases with painless jaundice in which the jaundice is due to stone in the common duct. This seems to me to make it worth while to emphasize the point that the group of patients with painless obstructive jaundice who have been considered as entirely hopeless can be relieved. I believe that exploration should be done in all of them. Stones in the common duct may cause this type of jaundice and they can be removed. Secondly, I think it wise to emphasize the beneficent results one can obtain, even in cases of carcinoma of the head of the pancreas, by anastomosis of the gallbladder and some portion of the gastro-intestinal tract. I do not know of any palliative operation for cancer that gives greater benefit to the patient. I have several patients now who are alive two years and a half after this procedure. I believe that because of these two possibilities all patients presenting conditions of this type should be operated on. Dr. Clute also mentioned that hemorrhage is the bugbear of the surgeon operating in cases of this type. There is no way of foretelling whether or not bleeding would occur in any given case. There is no direct ratio between the chance of hemorrhage and the length of time of jaundice. The bleeding time and the clotting time are not accurate indexes. Sometimes they indicate that hemorrhage is to be expected and it does not occur; again they are perfectly normal and postoperative hemorrhage occurs. Since Linton's paper in March I have been using the sedimentation test on this group of cases. Of about fifteen patients of this type with obstructive jaundice, in five the test was positive; that is, the sedimentation rate was very rapid, running from between 40 and 50 mm. in thirty minutes. In all of these positive cases postoperative hemorrhage occurred. One of the patients died.

Dr. Howard M. Clute, Boston: I, as a surgeon, am particularly impressed with the paper presented by Dr. Bockus and his co-workers because it seems to me that surgeons need added help which this method offers. I have not used it. Certainly it should be used for the cases of upper abdominal distress and pain which at present are not understood and which in many instances in the last analysis come to surgical exploration. Anything that will increase knowledge and reduce the number of exploratory laparotomies should be used. The mortality in gallstone cases increases as the disease is prolonged and as stones enter the common duct, and if I may do anything with this common duct stone study, it is to emphasize the following: Yesterday in the Section on Surgery, Judd and Marshall discussed 160 cases of common duct stone. They reported that 20 per cent or more did not show jaundice before operation or at any time in their past history. They also reported a mortality of 6.8 per cent, which is the same mortality that I report in this group. Ordinary mortality in gallstone disease when the gallstones are limited to the gallbladder, is from 1 to 3 per cent over several years, and the fact that it is more than doubled when the stones are in the common duct, is most significant. I would urge finally that innocuous, harmless gallstones, from the surgeon's point of view certainly—and I believe that point of view should be held by all of us—do not exist, and I believe that if these crystals are found and can be interpreted as pointing to gallstones, or if, by any method, one can discover gallstones, the time for medical treatment as such has ceased and, the patient's condition permitting, the moment for surgical intervention has arrived.

FAMILIAL NEUROSYPHILIS [*]

CHARLES C. DENNIE, M.D.
Assistant Professor of Dermatology, University of Kansas School of Medicine
KANSAS CITY, MO.

The idea that persons with active syphilis do not rear large families must be abandoned. In the old days, before the more complete diagnostic methods were in use, familial and especial familial neurosyphilis was often overlooked. It is true that the families who had the somatic type of syphilis were usually small, but those who had the neuro type were often large.

NEUROSYPHILIS IN INFANTS

Fifty-eight per cent of syphilitic infants have some involvement of the central nervous system, but the greater percentage of those so affected have the pure meningeal type. This finding suggests that the brain and spinal cord are not particularly selected by *Spirochaeta pallida* for especial attention but that the condition is a manifestation of general infection in the same manner in which the liver, spleen, bone and joints are involved.

NEUROSYPHILIS IN CHILDREN

In older children, the proportion of neurosyphilitic involvement, even without treatment, drops to about 25 per cent. One must assume that, in spite of the number of infants who died before the family was examined, the neurosyphilitic involvement of many of these children has retrograded without treatment until the spinal fluid is absolutely negative for all syphilitic tests, whereas, had these children been examined during infancy, one would have found the percentage of neuro-involvement much higher.

Positive results of tests of the spinal fluid of children which have persisted through infancy into childhood

must be regarded with more seriousness than the positive observations of infantile syphilis, for it means that a deeper and more widespread involvement has affected the brain and spinal cord and that it is not merely a meningeal involvement. It is from this type of child whose spinal fluid reaction is persistently positive that the great class of neurosyphilitic patients are drawn. Cases of dementia paralytica, tabes, optic atrophy or the paralyses of different types, and those presenting mental manifestations are classified as degenerative.

The history of one family will show clearly how persistent positive reactions in the spinal fluid may endure through infancy and childhood and result in more serious involvement of the cerebrospinal system.

The father and mother while young were tabetic and all five of the children gave marked positive reactions in the blood and the cerebrospinal fluid, including the infant, who was brought to the clinic because of secondary skin manifestations. The mother stated that all the children except the eldest, who is now 11 years of age, had the same skin manifestations as the youngest soon after they were born. The physical aspect of all except the eldest was greatly modified by the disease.

The type of disease in the parents does not at all determine the type of disease in the child. A study of these families makes one feel that neurosyphilis is as often not transmitted as it is transmitted to the offspring. One often sees children whose mother or father has neurosyphilis and who are affected with interstitial keratitis and bone syphilis without any evidence of neuro-involvement; and, on the other hand, children are seen with bone syphilis and involvement of the central nervous system whose parents show no evidence of neurosyphilis. In the main, familial neurosyphilis can be roughly grouped into four classes.

THE CHILDREN OF A FATHER WITH DEMENTIA PARALYTICA

While the wife of a father with dementia paralytica may often be affected with syphilis, she rarely develops dementia paralytica herself and it is entirely possible for her to escape the disease altogether. The children of this father may not escape the somatic syphilis, but they invariably escape any neurosyphilitic involvement.

After studying these tables, one can at least state that many children escape central nervous system involvement, although the father was a patient proved to have dementia paralytica who died of his disease. This observation testifies that the organism of syphilis which finally produces dementia paralytica in the affected individual is an attenuated form of the spirochete which the somatic system is able to control and is often able to eliminate, but because of the low resistance of the brain and spinal cord these organisms slowly injure and finally kill the vital cells of this great system.

In this series the father with dementia paralytica did not often transmit this type of disease to his offspring, although he did transmit syphilis to them.

THE INFLUENCE OF INCOMPLETE, EARLY TREATMENT IN THE PRODUCTION OF DEMENTIA PARALYTICA IN CHILDREN

The use of an insufficient amount of treatment in syphilis in adults will sometimes precipitate a serious neuro-involvement.

When haphazard methods are used in infants, the same disastrous result often occurs. By insufficient treatment the spirochetes can be transmuted into the neurosyphilitic type, or they can be made arsenic-fast so that further treatment with the arsenicals after a period of time is not effective. At the present time I have several cases which belong to this group.

R. S., a boy, aged 10 years, is the oldest of five children. The father and mother are both syphilitic but have no evidence of neurosyphilis. As an infant he received a few doses of neoarsphenamine in the buttocks and no further treatment until two years ago, when he received a course of sulpharsphenamine. When seen in the clinic at the age of 9 years, he had a typical taboparesis with classic manifestations. The other four children showed no evidence of syphilis, except that they had a positive Wassermann reaction and had no treatment. Examinations were absolutely negative in the cerebrospinal fluid and there was no evidence whatever of neurosyphilis. Only this case will be cited because the others in all essential points are the same. Thus we are confronted with a paradox.

Parents with dementia paralytica nearly always beget children free from central nervous system involvement, while, in one case, syphilitic parents free from neurosyphilis have a child in their family who developed the most fatal of all neurosyphilitic involvement (dementia paralytica).

THE CHILDREN OF PARENTS WHO HAVE TABES DORSALIS

An entirely different picture is presented when the parents are tabetic. In this type the disease is nearly always transmitted to the children and nearly all of them show involvement of the central nervous system or they show no involvement at all. The oldest child seems to be as badly affected as the youngest. A study of the accompanying tables impresses one with the persistence with which neurosyphilis was transmitted to the children, one after another. It demonstrates the fact that one is dealing with a more virulent organism in this type than in dementia paralytica. The patient with dementia paralytica often dies from his disease; his famly does not develop it; on the other hand, the tabetic patient does not die from his disease but he often transmits neurosyphilis to his entire family.

A comparison of the cerebrospinal fluid before and after treatment in this family is interesting. It will be noted that not only all of the children receive the routine arsphenamine, but also all were successfully treated by malaria, and in less than one year's time the cerebrospinal fluid of all except one became entirely normal.

In the T. family not only did the infants show positive evidence of syphilis in their central nervous system, but they also had marked skin eruptions over the entire body and involvement of the bones and joints.

The mother contracted her syphilis at the age of 15 years and at the age of 22 well developed tabes dorsalis with Argyll Robertson pupils and loss of knee kicks. In the second group I have shown that the children of tabetic parents often inherit the disease in the form of neurosyphilis, which may later develop into true tabes.

CEREBROSPINAL SYPHILIS IN THE FATHER OR MOTHER, OR BOTH

In most of these families the father shows more evidence of cerebrospinal syphilis than the mother. The transmission of syphilis to the children occurs in a strange manner. Usually one child, and that the eldest, will develop tabes or dementia paralytica. The rest of the children will be free from the disease so far as neurosyphilis is concerned. O'Leary's experience is the same as mine, excepting that in his families the youngest child of the family more often bore the brunt of the disease. A study of the tables reveals the fact that while the oldest child has typical juvenile dementia paralytica, both from a physical standpoint and from the serologic aspect, none of the other children show signs of neurosyphilis either serologically or actually. It is hard to explain this strange happening. One might hazard a guess that the parents being young when they married and the disease being young in the father, the vigorous, natural immune forces of both parents largely overcame the disease in a short while, so that the brunt of this transmitted infection was borne by the eldest child. In O'Leary's cases the youngest child who

The course of treatment consisted of neoarsphenamine and ten intramuscular doses of mercury or bismuth.

was affected by neurosyphilis was the child of old age when the natural immune forces of the body were at a low ebb and the parental syphilis once more becomes vigorous, that affecting the youngest child.

My conclusion in this class of disease is that when the parents are affected with cerebrospinal syphilis, in many instances only one child is affected with neurosyphilis and that is usually the eldest, while the other children escape any evidence of neurosyphilis and may even escape syphilis altogether.

The fourth and last class presents the strangest group of all.

The father and mother present no signs of neurosyphilis, although they undeniably have that disease. The oldest child will some time present some type of neurosyphilis and the rest will be free from this type of disease.

In the C. O. family the oldest child died from hemorrhagic cerebritis, precipitated by neoarsphenamine. It will be observed that the reaction of her blood was absolutely negative while her cerebrospinal fluid was positive. The younger children had positive reactions in the blood in various degrees excepting in the youngest, and without exception all have negative reactions in the cerebrospinal fluid. The only external signs of syphilis in this family was the nasal spur and saddle nose. In a critical survey of the families presented in these tables it will be noticed that usually the first child is affected with neurosyphilis and the rest are free, although in some instances it picks out a child here and there but does not affect the entire family.

TREATMENT

The treatment of children with neurosyphilis presents as many difficulties as the management of adult syphilis of the same type.

The ingenuity of the therapeutist is taxed to the utmost. In the last year malaria has been added to the armamentarium and with decided success. It can be used in any child over 1 year of age. The procedure is fraught with danger and one must be constantly on the alert to terminate it. This form of therapy will be taken up in a separate paper.

COMMENT

A general view of familial neurosyphilis impresses the investigator with its tragic hopelessness. While the patient with dementia paralytica does not as a rule transmit neurosyphilis to his offspring, his heritage of inferior mentality and substandard physique is almost as bad. The neurosyphilitic children of tabetic parents respond to treatment, and one is apparently able to arrest the progress of the disease, but their whole life will be hampered by treatment and limited by observation. And, while they would have died without treatment, they will probably become perpetual charges of society because their treatment has been half-way successful.

CONCLUSION

One must say that with the exception of locomotor ataxia there is no evidence that there is any special neurotrophic strain of *Spirochaeta pallida* transmitted from the parents to the children. This statement is supported by the following facts: In the most severe type of all these diseases, dementia paralytica, the father does not transmit his neurosyphilis to the children through the mother. It is perfectly possible for a father and mother who have no evidence of neurosyphilis to transmit a syphilis to their children that will eventually transmute itself into dementia paralytica or tabes and that will affect only one child. Furthermore, parents who have neurosyphilis or other types than dementia paralytica or tabes may transmit, and often do transmit, syphilis to their offspring in this peculiar manner: the oldest child dies of dementia paralytica and none of the other children have any neurosyphilis at all. As a final word, one must say that in familial neurosyphilis it cannot be proved that a neurotrophic strain of *Spirochaeta pallida* is transmitted, excepting in tabes dorsalis.

904 Grand Avenue.

ABSTRACT OF DISCUSSION

Dr. Paul A. O'Leary, Rochester, Minn.: The theme throughout Dr. Dennie's presentation dealt with the question of specific strains of *Spirochaeta pallida* in congenital neurosyphilis. Perhaps I should say that he presented evidence to support the idea that there are no specific strains of the organism. From a study of family groups in which one or more of the same family acquired syphilis from a different source, the bulk of the evidence was decidedly against there being a specific strain of the organism but highly in favor of the conception that the soil on which the organism grew determined the course of the infection. My experience with congenital syphilis confirms this observation. In fact, the few examples of syphilitic families in which neurosyphilis predominates throughout the infected members is decidedly rare in contrast to the syphilitic families that manifest a variety of forms of syphilis. I have been repeatedly impressed by clinical observation that evidence is still lacking in support of the existence of specific strains of *Spirochaeta pallida*, notwithstanding laboratory studies to the contrary. It is difficult to appraise the results of the treatment of congenital neurosyphilis, because it frequently not only is transient but also is a bizarre disease. For example, it is unusual to find a patient with frank juvenile tabes because manifestations of cerebrospinal syphilis or general paralyses are usually found in the same child. The few cases with outstanding therapeutic results linger long in the mind, while those who have progressed to juvenile paretic states are forgotten. I have found malaria therapy of value but less successful than in acquired syphilis. The inference to be drawn from a discussion of congenital neurosyphilis is that spinal fluid examinations should be done on all children at the time the diagnosis of congenital syphilis is made or shortly thereafter. This idea has been accepted as essential in the adequate care of patients with acquired syphilis, but in congenital syphilis the need for such a procedure has not been sufficiently emphasized or accepted.

Dr. Charles C. Dennie, Kansas City, Mo.: The point brought up by Dr. O'Leary is, perhaps, one of the most important points in the presentation, especially in the cases in which clinically there are a great many different types of involvement of the nervous system other than syphilis. It brings out the fact that every child who has a nervous disease that cannot be classified should have the benefit of a lumbar puncture. In some instances it will be found that this child apparently is the only one in the family who has syphilis, and sometimes it will be found that this disease of the nervous system will clear up under antisyphilitic treatment. Every child who has locomotive difficulty that cannot be definitely classified deserves a lumbar puncture, for in many of these cases the clinical symptoms are due to cerebrospinal syphilis.

The Schizothymic Temperament.—The person of average schizothymic temperament shows a tendency to be independent of others; that is to say, he tends to be "introvert" rather than "extrovert' (in the sense of Jung). He does not vibrate in sympathy with his surroundings; he likes to be alone rather than with other people. But if he remain healthy, he may do excellent work; many great scholars, rulers and aristocrats have been asthenics of schizothymic temperament.—Barker, L. F.: Psychology and Medicine, Porter Lectures, Series 1, University Extension Division, Kansas City, 1930.

SCHÖNLEIN-HENOCH'S PURPURA WITH INTRA-OCULAR HEMORRHAGE AND IRITIS

REPORT OF A CASE *

WILLIAM L. BENEDICT, M.D.
ROCHESTER, MINN.

The syndrome which came to be known as Schönlein-Henoch's purpura was called to attention by Henoch[1] in 1874. He reported five cases, all in young persons, in which cutaneous eruptions and articular swellings were followed by colic, vomiting, intestinal hemorrhage, pain and moderate fever, without involvement of the heart. Groups of cases have been reported since in which various symptoms have been emphasized; some authors have remarked on the prevalence of arthritis, and others have remarked on the colic and abdominal pain. The reports have in common notation of the hemorrhages into the skin, of free blood in the intestinal tract and of nephritis. Schönlein, about 1832, emphasized the articular symptoms, which in many cases may be the first and most pronounced symptoms noted. The disease in later years has been referred to as Schönlein-Henoch's purpura, although according to Osler the first description of the condition was given by Willan in 1808.

Goldstein[2] wrote: "Schönlein-Henoch's purpura is related to a large group of anaphylactoid disorders, such as serum sickness, food allergy, angioneurotic edema and urticaria, but allowing for individual variation the name is best reserved for the joint and kidney symptoms."

The disease occurs most frequently in young females. It rarely occurs in patients aged less than 3 years, and is most common in the second decade of life. The onset of the attack varies. There may be headache, anorexia and prostration, or the initial features may be a purpuric outbreak or an attack of abdominal colic. Irregularity in the onset, duration and character of the symptoms in this type of purpura is well recognized. Purpura or the erythematous group of cutaneous lesions often occurs before, and sometimes long after, the abdominal crises.

That a definite chain of symptoms constituting the disease exists is now universally recognized but, as Henoch stated, a link in the chain may be missing. Convulsions of an epileptiform type complicated a case reported by Grace.[3]

The ocular signs of purpura are few. Rarely, the lids are the seat of hemorrhagic deposits, although hemorrhages into the optic nerve and retina have been noted, as well as optic atrophy. Motolece[4] saw bilateral papillitis, with alternating convergent strabismus, from rheumatoid exanthematous purpura. The patient was a child, aged 3 years. The day after the onset of febrile symptoms, purpuric patches appeared on the skin of the abdomen and limbs, and convergent strabismus developed. In one eye, hemorrhages were associated with the papillitis.

So far as I have been able to learn from a search of the available literature, ocular hemorrhages and iritis with corneal opacification have not been reported as a complication in Schönlein-Henoch's disease, although it is logical to presume that, since rheumatoid arthritis, with hemorrhages into the skin, is not uncommon, some cases bordering on this disease must have been observed. The difficulty in arriving at a diagnosis of the malady lies in the variability and inconstancy of the symptoms; a complete chain seldom is present. Acute iritis, with intra-ocular hemorrhage and staining of the cornea with blood, was seen in Schönlein-Henoch's syndrome, together with the following history and observations:

REPORT OF CASE

A woman, aged 30, was referred to the clinic and came under my observation in August, 1927, because of an attack of acute iritis and keratitis in the left eye. The history of this patient could not be considered relevant at this time and not until two years later did symptoms develop which, when regarded in connection with incidents that had occurred in previous years, permitted a satisfactory explanation of events that had caused the loss of the right eye and threatened to deprive her of what sight she had in the left.

The patient had been a healthy child until she was 4 years old, when she had scarlet fever, complicated with severe rheumatic fever. Subsequent to this attack of rheumatic fever she was unable to walk for a year. She slowly recovered her strength, however, and was in good health until she was about 14 years of age. (She remembered that as a child she had had frequent epistaxis.) She began to menstruate four months before she was 12 years of age. Menstruation was natural and regular but was associated with severe cramps for three or four days, which required her to go to bed at each period.

At the age of 14 years the patient had a severe attack of measles, associated with general anasarca and nephritis. Her recuperation was rather slow and she spent considerable time in outdoor exercise in an attempt to regain her strength. Before she had fully recovered her usual health she was thrown from a horse, striking on her head, and was unconscious for five hours. Following this injury the menses stopped for six months, but about three times during the six months she had severe pains in both lower quadrants of the abdomen. At the end of six months she consulted physicians, who prescribed medicine; the periods were resumed but were irregular, from four to seven weeks apart. She had a great deal of cramping pain with the menses, which required her to be in bed two or three days. At 18 years of age she had an attack of rheumatism and what was diagnosed as purpura hemorrhagica, for which she spent several months in the hospital. The following year, because of the severe pains in the lower part of the abdomen, physicians thought she had appendicitis, and the appendix was removed.

Following the operation, the menstrual periods stopped altogether for five months, and thereafter regularly every four weeks she had epistaxis for four or five days. There was also vomiting of blood, associated with severe pains and cramps in the lower part of the abdomen. Occasionally there were small hemorrhages into the skin of the lip. This condition continued until she was 21 years of age, when she was referred to the Mayo Clinic in 1920 because of the menstrual disturbance and so-called stomach trouble and nervousness.

Up to that time the patient had not had trouble with her eyes, and at the time of her visit vision of the right eye was 6/6; of the left, 6/10. The media were clear, and ophthalmoscopic examination gave negative results. There were some convulsive movements and areas of anesthesia and other data which led to an opinion on the part of some of the examiners that she was suffering from chorea and of others that her symptoms could be accounted for on the basis of hysteria. She was sent home with a diagnosis of chorea. She did not return to the clinic until 1927, but in the meantime she spent considerable time in hospitals.

In this interim, the first trouble with the patient's eye occurred in the autumn of 1923, when, in October and November, she had iritis with corneal ulceration. Her tonsils were

removed in the latter part of that year. In 1920, when she was 23 years of age, she underwent uterine dilation and curettage to help reestablish natural menstruation. In 1921, she again entered a hospital for systematic study. Her complaints at this time were as follows: (1) no normal menstruation since the appendectomy five years previously, and in its place regular vicarious menstruation from the nose; (2) inability to urinate for eighteen months without either catheterization or enema, and (3) inability to eat or drink without vomiting three or four minutes afterward. The inability to eat or drink was corrected by passing a large stomach tube three times. The inability to urinate permanently disappeared after the bladder had been allowed to go unemptied for four days. That year extensive so-called purpura hemorrhagica developed, and lasted for six months. This involved every part of the patient's body at various times. At one time her hands were swollen to twice their usual size and were red with subcutaneous hemorrhages. At another time, two thirds of one thigh was a solid hemorrhagic area.

In 1923, an attack of iritis, with loss of vision in the left eye from hemorrhages, continued for about eighteen weeks. In 1925, the eye again became painful. An extensive search for foci of infection was made. Several teeth were extracted and a submucous resection was done. In June, 1925, the left eye became blind and was enucleated two years later, in March, 1927. The vicarious menstruation continued as before. In 1926, the nasal accessory sinuses were operated on.

Aug. 27, 1927, as has been noted, the patient returned to the clinic because of an attack of iritis of the right eye. Five days before she came to the clinic, severe headache came on which lasted for about three days. On the third day of the headache, the right eye became inflamed for the first time, and whereas hitherto she had been able to read fine print with ease without glasses, she had not been able to see more than moving objects for two days. The eye was painful. The lids were slightly swollen, the margins were covered with secretion, and the bulbar conjunctiva was markedly swollen and congested. The cornea and aqueous humor were cloudy, the iris was congested, and the pupil was 4 mm. in diameter and did not react to light.

Nothing significant was discovered in the general examination. The Wassermann reaction of the blood was negative. Roentgenograms of the thorax and nasal accessory sinuses gave negative information. Albumin or sugar was not found in the urine. The differential blood count was not significant of disease. Blood platelets numbered 210,000 in each cubic millimeter of blood. The coagulation time was five minutes; the bleeding time was one and a half minutes.

The patient was placed in the hospital to receive local treatment. Atropine was instilled into the eye every two hours, and hot compresses were applied three times a day. She was given 5 cc. of boiled milk intramuscularly, from which a slight reaction occurred. Very little change was noted in the condition of the eye. In addition to four injections of milk given intramuscularly, she was given twenty doses of 100 grains (6.5 Gm.) each of sodium salicylate in oil, by rectum, at intervals of four days. The eye gradually became clearer; the congestion receded and vision improved. In the early part of October she complained of considerable pain in the right upper abdominal quadrant. There was tenderness on pressure over the region of the gallbladder. She had been nauseated most of this time, and vomited most of her meals. October 17, the temperature rose to 101.2 F. The following morning it was normal. Examinations of the blood and urine at this time were not significant of disease. The patient was seen by medical and surgical consultants and was transferred to another hospital for observation in a surgical service with practically the same symptoms she had had for the past eight years. There seemed to be sufficient evidence of disease of the gallbladder to warrant cholecystectomy. This was done, Nov. 2, 1927, on which date the surgeon (Walters) reported negative results of exploration of the stomach, duodenum and pelvis. The pathologic report was of chronic catarrhal cholecystitis, strawberry gallbladder, and a single papilloma, 2 mm. in diameter. The surgeon felt that although the cholesterosis and papilloma explained the biliary colic, he did not believe they had any influence in the production of the intermittent pyrexia. Convalescence was uneventful, and the patient was dismissed from the hospital, November 18. She had two normal menstrual periods following this operation. Her vision gradually improved after she went home, and for several months she was able to continue with her work as a teacher of piano and mandolin.

The condition of the blood was studied by a clinical hematologist (Giffin), who felt that the history of intermittent swelling of the knees and ankles, with purpura, recurrent iritis and choreiform attacks, was more indicative of the rheumatic type of purpura than of purpura hemorrhagica.

In July, 1928, the patient had another attack of inflammation in the right eye and was blind for four weeks, after which the vision improved again and remained good until January, 1929. She returned to the clinic, Jan. 4, 1929, complaining of progressive blindness in the right eye, with frequent attacks of pain and redness. For several months, about every four or five weeks, she had had either excessive nosebleed or subcutaneous hemorrhages. Occasionally there would be no subcutaneous hemorrhage or nosebleed and the eye would become very red and painful, with diminution of vision. She felt well except for this vicarious menstruation and difficulty with the right eye. Although her sight had been sufficiently good for her to continue her work as a musician, the vision was now reduced to 3/60. There was peripheral contraction of the fields; intra-ocular tension was normal to palpation; the pupil reacted slightly to light. In the central portion of the cornea, over an area from 5 to 6 mm. in diameter, there was an interstitial crystalline deposit; the periphery of the cornea was clear. The opacity in the cornea was not sharply outlined; there was no vascularity of the cornea and no keratic precipitates. She was kept under observation for a few days until the eye became so badly inflamed and painful that it was felt necessary to put her in the hospital. Intravenous injections of typhoid vaccine were given, which produced a mild febril reaction. The circumcorneal injection disappeared, but th posterior surface of the cornea became completely covered wit keratic precipitates, giving a creamy appearance. Vision was reduced to perception of light. She was kept in the hospital under observation for five months. It soon became obvious that her condition responded in no way to the administration of salicylates or foreign proteins. The pain in the abdomen was so severe that daily injections of morphine were required to give relief.

Early in February, typical purpuric areas developed over the right buttock and right thigh. Preceding the hemorrhage into the skin, there was intense pain and burning for a few hours. Later, the right forearm and hand became markedly edematous, with much local pain, and these manifestations were followed by areas of hemorrhage which began as small spots and spread rapidly. After a few days the swelling would go down and the discoloration would disappear, only to reappear in some other part of the body. The legs, feet, hands and forearms were continually affected in a few shifting places, while a few large areas occurred on the buttocks, thighs and shoulders. The face, the anterior aspect of the thorax, and the abdomen were always free from this disorder. The condition was now diagnosed as Schönlein-Henoch's purpura. The hemorrhagic areas continued to form without interruption for about three months, and became gradually less extensive until the time of the patient's dismissal.

During the five months that the patient was under observation, the eye was continually intolerant to light. After several weeks, the congestion of the conjunctiva cleared away and the eye was less painful if the patient was left in darkness. The corneal surface never lost its luster. There was a dark brown stain of the substantia propria which was more dense near the center, where there were crystalline bodies; the opacity faded toward the periphery. The cornea gradually cleared, aided somewhat perhaps by the employment of heat and ethylmorphine hydrochloride, which were applied regularly. The patient was dismissed, May 30.

COMMENT

My experience has verified statements regarding the course of severe cases of Schönlein-Henoch's purpura, the irregularity of onset and of symptoms, and the apparent ineffectiveness of treatment.

ABSTRACT OF DISCUSSION

Dr. Lawrence T. Post, St. Louis: Dr. Benedict has presented an interesting case of Schönlein-Henoch's purpura during the course of which there occurred severe intra-ocular hemorrhage, iritis and keratitis. He has pointed out the clinical features of this type of purpura. The principal underlying differential point from other purpuras is that in this entity one is dealing with a disease of the capillaries and not of the blood. From every point of view this case fits into the picture of Schönlein-Henoch's disease. One hundred and sixty-five cases of purpura of all types seen in Barnes Hospital, the outpatient department of Washington University School of Medicine and the St. Louis Children's Hospital, in the last ten years, were reviewed with reference to pathologic changes in the eyes. There was doubt in many cases as to whether the disease was the so-called Schönlein-Henoch's or not. Unless a hematologic basis is used there are too many different clinical pictures associated with purpura to permit of many unquestioned diagnoses. The syndrome varies with the individual's response to the toxin. Of the 165 cases, 15 were probably Schönlein-Henoch's disease. Of the entire group, only 4 showed any eye changes and none of these were definite Schönlein-Henoch cases. In two there were small retinal hemorrhages and in two others conjunctival hemorrhages. As the author has said, there does not appear to have been recorded in the literature any case similar to the one he has described. The question arises whether the ocular condition was from the disease itself or from some extraneous factor. That massive intra-ocular hemorrhages should occur would seem not unreasonable, as the capillary structure of the eye might be involved in the same way as the capillary structure elsewhere in the body, and small retinal hemorrhages have been noted. Such a distribution in this patient seems more likely than in many other patients because of the extremely wide distribution of the hemorrhages, almost every part of the body having been involved. To account for the iritis and keratitis as due to the same agent as the purpura is certainly possible, but in view of the absence of similar cases it would seem perhaps more likely that some other source of infection was responsible, such as tuberculosis, cholecystitis, tonsillitis, appendicitis, scarlet fever or nephritis, all of which, except tuberculosis, had been found in this patient. In such a diseased individual it would probably not have required an especially virulent toxin to cause the lesions described.

Dr. F. Park Lewis, Buffalo: I have seen but one typical case, in a boy, aged 12, of Jewish parentage, a resident of Toronto. Eight days prior to his visit he had a severe chill followed by fever and delirium. He was ill for a week. With the chill developed great lameness, his arms and legs becoming useless because of the intense pain. He had previously had attacks of asthma but otherwise had been well. During the fever, petechial spots appeared on the arms and legs and by the following day had covered the entire body. Suddenly he lost the sight of the right eye. At the time of the examination, fingers could be counted at 4 feet. Extensive retinal hemorrhages were present. So far as I have been able to discover in the literature, intra-ocular involvements have not been noted. A peculiarly interesting fact connected with this case is that a sister, aged 16 years, had developed keratoconus. The origin of this form of purpura is as obscure as is that of keratoconus. It may be dependent on the absence of some element necessary to the integrity of the tissues; it may have an endocrine basis. In any event, it offers an exceedingly interesting field of research in the department of biochemistry, and the discovery of the missing element in Schönlein's disease may help to explain why the integrity of the cornea gives way.

Dr. William C. Finnoff, Denver: I should like to ask whether the patient showed any tendency to excessive bleeding after minor operations. Also whether the author has seen any reference in the literature to hemorrhage around the globe or in the region of Tenon's capsule or around the insertion of the ocular muscles. I have such a case at the present time that might fall into that category.

Dr. William L. Benedict, Rochester, Minn.: Answering Dr. Finnoff, the bleeding time and coagulation time show no variation from normal. There was no unusual bleeding after surgical operations. This patient had had a gallbladder operation which was uncomplicated. Other operations were done elsewhere but I do not know of any complications. The first eye was lost from intra-ocular hemorrhage and secondary glaucoma. The second eye on two different occasions was filled with a hemorrhage so dense that I was unable to see details in the iris. In both instances, that has cleared. After the first intra-ocular hemorrhage the vision returned to 6/6; after the second hemorrhage I had a letter from the girl saying she was back at work as a music teacher and able to see. The maximum visual acuity never was recorded, but there was nothing to lead me to believe that this patient had hemorrhages about the orbit other than this I have mentioned. It is commonly believed by those who saw the patient that the pains in the joints were due to hemorrhages into the synovial membranes and that the pain in the abdomen was due to infiltration of the omentum and membranes of the abdomen. There is a well known group of women who have repeated hemorrhages from the uterus that I think belong in this group, and I think it has been wisely suggested that many persons with hemorrhages of the eye belong to this group.

CAUSES UNDERLYING INCREASED INCIDENCE OF BROAD TAPEWORM IN MAN IN NORTH AMERICA [*]

TEUNIS VERGEER
Fellow in Medicine of the National Research Council
ANN ARBOR, MICH.

In a recent publication I [1] pointed out that fish-eating dogs must constitute an important reservoir of *Diphyllobothrium latum* Linnaeus, the broad tapeworm of man, in Canadian lake regions and that in some sparsely populated districts dogs may be the most important agents in bringing about the completion of the life cycle of this parasite and thus maintaining it by continually reinfesting nearby lakes with the eggs of the broad tapeworm.

In another recent publication I [2] reported the successful experimental infestation of two bears with the broad tapeworm. This experiment was performed because bears are common in northern lake regions where fish are infested with the larvae of this worm. Bears are known to eat fish during the spawning season in the spring when they can readily catch them. Bears, then, may also help in the reinfestation of fish with plerocercoids of the broad tapeworm by passing eggs with their feces into the water in which they often wade and swim. That several other carnivores may serve as hosts of the broad tapeworm was also indicated in this publication.

The present paper is a report on an expedition made during July and August of 1929 in the northern half of Minnesota and in Canada in an attempt to find proof for these contentions. The work has, accordingly, been limited to the incidence of broad tapeworm in dogs and bears.

Since Riley [3] had reported a broad tapeworm infestation in an Indian child from the White Earth Indian Reservation and since, in Canada, I [1] found that Indians

have many dogs and feed them on raw fish, I decided to visit the following three Indian reservations in Minnesota for the purpose of examining the Indians' dogs for broad tapeworm: White Earth Reservation, Mahnomen County; Red Lake Reservation, Beltrami County, and Cass Lake Reservation, Cass County. Only the Red Lake Reservation remains as a reservation, but many Indians still live on the two former reserves.

Aided in the collection of fish by Chief Warden Charles Masoner and his assistants, whom the Minnesota Department of Game and Fish kindly permitted to assist me, a preliminary examination was made of fish from one or more lakes on each of these reservations to determine whether there were infested fish that could be the source of infestations with adult worms in dogs. Plerocercoids were not found in any of a total of ninety-two fish from nine lakes with the exception of one plerocercoid of *D. latum* in each of two fish from Leech Lake, Cass County. Two dogs that were known to eat fish regularly were treated with appropriate doses of arecaline hydrobromide. Neither had *D. latum*. One of them was purchased and to it the two plerocercoids from fish of Leech Lake were fed. They failed to develop. Because infested fish were at least extremely rare in the lakes on or near these Indian reservations, no further attempt was made there to recover the broad tapeworm from dogs.

The vicinity of Ely, Minn., is a known endemic area for *D. latum*.[4] Ward,[5] Essex[6] and Magath,[4] who directed or made a study of the broad tapeworm there, have paid little attention to the dog as a carrier of *D. latum*. Ward[7] reports that "the adult parasite was recovered . . . also from the dog as the result of natural infestation." While in Ely, I learned that one specimen of *D. latum* had been collected by Ward's party from one husky. Ward[7] also calls attention to the immature *D. americanum* collected by Hall and Wigdor[8] in Detroit and suggests that it may be immature *D. latum*. In an examination of twenty-two dogs from Detroit I discovered one adult *D. latum*, and from La Rue I received another adult broad tapeworm collected by W. A. Troy from another dog from Detroit. These tapeworms were both natural infestations.

Since little work had been done on the dogs in and about Ely, I decided to examine some of the dogs there. With the aid of Chief Warden William Hanson and his assistant Mr. Graig, a preliminary examination of fish was also made, and, as previously reported by Magath,[4] in Long Lake I found that *Esox lucius* Linnaeus, the great northern pike, and *Stizostedeon vitreum* Mitchill, the wall-eye, were heavily infested with plerocercoids of *D. latum*.

I had previously examined perch, *Perca flavescens* Mitchill, from Portage Lake, Houghton County, Mich., another endemic area,[9] but had never found any infested with *D. latum* plerocercoids although Magath[4] reported them from Long Lake. Two out of four perch from Long Lake I found infested: one with two, the other with three plerocercoids. These were fed to a dog that had previously been treated with arecaline hydrobromide, had not passed tapeworms and was negative for eggs of *D. latum*. One plerocercoid developed into a small *D. latum*.

It is probable that the food eaten by perch in Portage Lake, Michigan, is very different from that in Long Lake, Minnesota. The perch in Portage Lake fed almost exclusively on crayfish. This may account for failure to find them infested there.

Attempts were made to collect trout from Burntside Lake and Long Lake because Magath[4] also reports these fish to be capable of taking the infestation, but I was informed by local game wardens that trout had never been taken from Long Lake and only rarely from Burntside. A close scrutiny of Magath's work reveals not a single record of a plerocercoid of *D. latum* taken from trout and only one record of a single plerocercoid found in other fish from Burntside. Magath states, however, that he found only about 10 per cent of the fish in Burntside Lake infested with larvae.[4] In the examination of twenty-three wall-eyes, one great northern pike, and two burbot, *Lota maculosa* Le Sueur, from Burntside Lake, I did not find a single plerocercoid. Even with the expert aid of Mr. Hanson and his assistant, we were not able to take a single trout. A total of thirty-five trout, twenty-six *Cristovomer n. namaycush* Walbaum, and nine *Salvelinus f. fontinalis* Mitchill have been examined by me[9] from the endemic area in the upper peninsula of Michigan and twelve very large trout, *Cristovomer*, from Lake Nipigon, an endemic area in Ontario.[2] In not a single instance has a broad tapeworm plerocercoid been found. Although some species of trout in Europe are known to be carriers of *D. latum* plerocercoids, the American species of trout must be considered to be free from these until the contrary is proved. The results of my examination of fish from lakes near Ely are in partial disagreement with those of Magath in that I find infested fish in lakes comparatively far from Ely or any other city. In fact, I found plerocercoids in fish from lakes as far northwest as the Canadian border and the previous year I found infested fish in practically uninhabited regions about a hundred miles north of this point across the border and tried to explain their presence by the common occurrence of bears[2] and other carnivores which I believed must serve as hosts.

Magath assumed that the inhabitants of Ely were largely responsible for the pollution of Long Lake with broad tapeworm eggs and estimated that perhaps as high as 10 per cent of the inhabitants were infested with the adult *D. latum*.[4]

I intend to show that, although man may originally have been a rather important agent in causing the infestation of fish in Long Lake, the most important agent, the dog, has thus far not been recognized as such.

In my work I have limited myself to the examination of dogs, and in the form of a suitcase full of adult specimens of *D. latum* from dogs I have collected the most convincing evidence that they are the greatest source of infestation in the vicinity of Ely. Fifty-two dogs have been examined. It should first of all be observed that most of these dogs have been better cared for than the average. Twenty-three belonged to the Department of Fish and Game of Minnesota, three to Canadian rangers and four to a dog breeder; the remaining twenty-two belonged to private owners. To all these people I am indebted for allowing me to treat,

in many cases, their valuable dogs. I am also indebted to Mr. Graig for his courageous assistance and to the Department of Game and Fish of Minnesota who kindly allowed Mr. Graig to give me his time.

The results of five treatments could not be determined. Other tapeworms than *D. latum* were removed from only four of these fifty-two dogs, an unusually low percentage of infestation. Fifteen dogs, more than 30 per cent, had one or more adult specimens of *D. latum.* These fifteen infested dogs had together a total of sixty-five adult and nine or ten immature specimens of *D. latum,* an average of nearly five each. The greatest width of these worms was from 4 to 16 mm., most of them more than 10 mm. wide. The length was from 40 to 270 cm.

Several of the fifty-two dogs were regularly given an anthelmintic treatment and had been treated rather recently. Moreover, nearly all the dogs belonging to the Department of Game and Fish were kept in cages. Fish was used only occasionally as food and the food was nearly always cooked. The proportion of infestation (21 per cent) of the dogs of the department is far below that of the dogs in Ely (55 per cent), while this establishment is only 5 miles from Ely and on the shore of Fall Lake, into which Long Lake drains. This 21 per cent infestation might still be much lower if visitors who come to see the dogs could always be prevented from surreptitiously giving dogs freshly caught small fish. Four of its five infested dogs had received an anthelmintic treatment the preceding March and had in all only five broad tapeworms, while the average number of tapeworms for all other infested dogs treated was six each. It is remarkable that a single dog belonging to the Canadian rangers, far from any town, had at least twenty-four specimens of *D. latum,* of which five or six were immature.

There are, of course, many more dogs in the vicinity of Ely, but it is believed that the infestations in these fifty-two dogs are representative of those in dogs in this area and that the work done will suffice to demonstrate the importance of the dog as a carrier of the broad tapeworm.

Some time was spent in an attempt to determine in what ways the millions of eggs passed daily by all these tapeworms could get to water in which they could develop and ultimately infest fish. The establishment of the Department of Game and Fish is located at Winton on top of a hill which slopes steeply down to Fall Lake. Drainage from temporary fecal deposits secured by cleaning the cages and from the few dogs that were tied up outside because no cages were available may bring eggs into Fall Lake. In winter these huskies are used for sleighing over the frozen lakes and thus they deposit eggs on the ice. Whether winter freezing is harmful to the eggs of the broad tapeworm is not known. The heavily infested dogs belonging to the Canadian rangers live with them on the shore of Basswood Lake and run free. Their feces are washed from the beach by the waves caused by every strong wind and thus they infest water in the wilderness a considerable distance from any town or habitation. Most privately owned dogs in Ely run loose on the streets from which, with every rain, broad tapeworm eggs may wash down into the storm-sewers, which discharge into a settling tank which opens in Long Lake. This tank may not always eliminate all eggs. Many dogs accompany people to the shores of lakes, nearby or distant, and there defecate on the beaches. If the settling tank of the Ely sewerage system is effective in eliminating broad tapeworm eggs, then the danger of reinfestation by eggs passed from man is almost nil and dogs or other carnivora must be almost wholly responsible for the maintenance of the infestation in the lakes near Ely.

INFESTATION OF BEARS WITH THE BROAD TAPEWORM

In the beginning of this paper, mention was made of the bear as a possible natural host of the broad tapeworm. Near the city of Ely bears are not found, but a few miles north and west of Ely in a territory used only for resorting purposes and farther north into Canada bears are quite common. In an attempt to determine whether bears in the wild state had broad tapeworm, I collected feces of bears at various places where resorters reported that they had seen them almost daily feeding on the refuse from tourist camps. Only strictly fresh feces were collected, and the number of samples taken equaled the number of bears reported seen at any one place. To prevent possible duplication where one bear might have defecated twice within a very short time, two apparently similar samples were not taken within walking distance of each other.

In this manner a total of ten fresh samples of feces of bears were obtained. Eggs typical of *Diphyllobothrium latum* were found in four instances. In two of these the eggs were extremely numerous; in one, rather numerous, and in one only a small number of eggs were found on any one slide of the decanted precipitate of the sample of feces.

This proves that wild bears in their natural state are infested with the broad tapeworm and confirms my previous work on this point.[2]

Although bears cannot be prevented from catching fish in spring, in this area between Ely and the Canadian border and elsewhere they can be prevented from feeding on camp refuse by fencing the refuse dumps or by burying offal in deep holes or by burning it. One wall-eye from Basswood Lake was infested with two plerocercoids of *D. latum.* I happened to obtain this fish after it had been boned at a camp on the shore of this lake, just before the bones and adhering flesh were discarded to go to the dump. The two fillets from either side of the fish were free from *D. latum* larvae but in the flesh adhering to the bones of the back I found the two plerocercoids. Had I not found these, a bear certainly would have eaten them. This example may bring home the importance of preventing wild carnivora from feeding on camp refuse in lake regions.

Dogs should never be allowed to eat raw or insufficiently cooked fish or viscera of fish.

Such prevention would aid materially in the reduction of infestation by the broad tapeworm.

SUMMARY

Investigation has demonstrated that dogs in the region extending from Ely, Minn., north into Canada are heavily infested with *Diphyllobothrium latum,* the broad tapeworm of man, and are largely responsible for the continued infestation of fish with the larvae, which may develop in man.

Numerous eggs typical of those of *D. latum* were found in four of ten samples of feces of wild bears.

Dogs and wild carnivora may cause the further distribution of this parasite into uninhabited, as well as heavily settled, regions in North America.

REACTION TO ANTIMENINGOCOCCUS SERUM

PRELIMINARY REPORT *

ARTHUR DURYEA, M.D.
HONOLULU, T. H.

During several quarantine periods for epidemic cerebrospinal meningitis at Maliola Island, Honolulu, T. H., early diagnosis and prompt treatment proved the most effective agent in obtaining a low mortality rate (14 per cent).

Quarantine conditions were such that it was possible to isolate and treat patients in the very earliest hours of the disease. It was decided that any patient with the following signs and symptoms should have a diagnostic spinal tap and prophylactic administration of antimeningococcus serum: (1) headache; (2) fever (over 38 C., or 100.4 F.) with no obvious cause; (3) either a positive Oppenheim reflex or Gordon reflex. The classic textbook picture of retracted neck, Kernig's sign, Babinski's sign, all appear too late to be of value in early diagnosis.

In many of our cases tapping was done so early in the disease that clear spinal fluid under increased pressure was found on the initial tap, but with no abnormality of chemistry or cell count. On subsequent examinations a high cell count, absent sugar, positive globulin and characteristic organisms were found. In some cases several days elapsed before organisms were found either by culture or by direct smear. It seemed necessary, therefore, to ascertain the response of normal individuals to the intraspinal administration of antimeningococcus serum.

Two normal healthy men who had not been exposed to epidemic cerebrospinal meningitis were selected as controls. Twenty cubic centimeters of spinal fluid was withdrawn by cisternal puncture and replaced by 20 cc. of a concentrated serum preparation. Subsequently six cisternal and lumbar punctures were done, and fluid removed for examination only.

Case 1.—Four hours following the administration of serum the patient was nauseated and complained of a slight headache. His temperature never went above 37.6 C. (99.7 F.), and no abnormal neurologic phenomena developed.

Case 2.—Five hours after administration of serum the patient complained of headache, was nauseated and vomited several times. His temperature three hours after the administration of serum was 38 C. (100.4 F.); six hours after, 38.2 C. (100.7 F.); nine hours after, 37.8 C. (100 F.), and thereafter normal throughout two weeks of observation. The patient developed absolutely no abnormal neurologic phenomena. In spite of the repeated cisternal punctures, which were done without local anesthesia, there was only slight soreness in the region of the puncture and no reluctance to submit to puncture.

Reactions Observed *

		Cell Count	Adjusted Count	Sugar	P. N.	Necrosis of P. N.	Monos.	Globulin	R. B. C. in Sediment	Bac.	Culture	Condition of *Fluid*

ALLERGY AND THE ACID-BASE BALANCE

HARRY BECKMAN, M.D.
Professor of Pharmacology, Marquette University School of Medicine
MILWAUKEE

In presenting at this time the hypothesis that there is an intimate connection between the state of allergy and the acid-base balance in the body, I do not wish in the least to disparage the sensitization theory and the work of desensitization that has been built upon it. These things are of immense value; indeed, they constitute the greatest advance that has been made in the understanding and treatment of the allergic ailments. For instance, it is nowadays known that a normal nonallergic individual can be passively sensitized locally by the intracutaneous injection of serum taken from an allergic individual, and that if the recipient then takes an article of food that affects the donor the locally sensitized area responds by reaction; this is undoubted proof of the existence of such a thing as sensitization. Furthermore, it is known that carefully performed skin tests will sometimes make it possible to detect the offending substance in the environment, and that often by withdrawal of the patient from the substance or the substance from the patient, or by desensitizing him to it by injections or by the feeding of increasing doses, one is able to alleviate markedly or cure his malady.

But there are certain other things that have not been learned as well: 1. Skin tests are certainly not infallible[1] and give positive reactions in only about 50 per cent of the cases. 2. Clinical cure can exist in the presence of the offending substance in spite of the fact that the skin reactions remain positive[2]—witness Walker's[3] recent report of 100 patients with pollen hayfever apparently cured by desensitization, in 44 of whom the skin tests were not changed at all, and in only 22 of whom were marked positive reactions changed to negative. 3. Numerous persons are convicted of sensitization by skin tests though they never throughout their lives manifest any allergic symptoms. 4. Allergic persons are peculiarly susceptible to emotional influences and atmospheric conditions, which facts accord but ill with the exclusive immunologic basis on which sensitization-desensitization studies have been placed. 5. A sea voyage or a sojourn at a high altitude often brings relief to a sufferer, whether he is pollen sensitive or not. 6. The present rewriting of the whole of immunology by Manwaring and his associates will soon necessitate restating this sensitization hypothesis in the new terms, a task that may be found somewhat difficult.

---

[1] Eyermann, C. H.: Tr. Am. Laryngol., Rhin. & Otol. Soc. 33:477, 1927.

Therefore I think it might be of some value to medical science if enthusiasm for the exclusive study of sensitization and desensitization were abated, at least to the extent of admitting that there are several other factors, perhaps of equal importance, contributing toward the make-up of that whole which is known as the allergic state.

UNDERLYING METABOLIC DYSCRASIA

The allergic diseases have in common the following characteristics which can be looked on as extrinsic manifestations of an intrinsic metabolic imbalance, theoretically ascertainable by careful chemical and physical rather than immunologic examinations of the blood. (*a*) The tendency is definitely hereditary. (*b*) These diseases are rarely fatal, though they cause great suffering and inconvenience. (*c*) They are not infectious. (*d*) Emotional upsets sometimes precipitate an attack. Bénard and Joltrain[4] have recently published a paper on emotional asthma, and Lamson[5] has recorded a case in which a sudden surprise slap on the back would invariably precipitate an attack of asthma; and he mentions other patients who could either precipitate or control attacks by drinking hot, cold or carbonated waters. These observations certainly lend little support to the allergen-antiallergen reaction as being the sole mechanism involved, but they do support those who, both in laboratory and in clinic, are with increasing frequency showing that emotional disturbances profoundly affect the metabolic processes. Thus, Barbour and Hamilton,[6] in discussing their new method of determining the specific gravity of fluids say: "In view of the well established but neglected fact that relatively slight emotional disturbances are associated with anhydremia, one wonders how many really normal blood samples have ever been taken." Excitement increased the blood concentration in their dogs sometimes as much as 10 per cent. (*e*) A person may be the victim of several of these diseases at the same time. (*f*) The afflicted person continues to be susceptible to attacks of these diseases throughout life, though the incidence and severity sometimes decline with advancing years. (*g*) Single attacks begin quite abruptly but usually decline gradually. (*h*) Between attacks there are no disturbing residual symptoms save in those instances in which there is developed a characteristic pathologic condition purely as a secondary affair. (*i*) The attacks are often much abated and sometimes entirely suppressed during the course of certain intercurrent maladies noted for their effect on the general metabolism.

In view of the foregoing considerations, the hypothesis may be tentatively proposed that allergic individuals form a relatively small group of persons who over and over throughout their lives suffer from a few diseases to which the great majority of mankind is not susceptible, the immunity of the latter being due to the fact that they are at all times in a state of complete metabolic balance denied to the allergic minority.

POTENTIAL ALKALOSIS AS CAUSATIVE

A definition is necessary here. By "potential alkalosis" I mean the tendency of an individual to store up too much reserve alkali, or, which means the same thing, to neutralize too rapidly or too effectively the acid substances that are constantly being liberated into the blood stream during the course of normal metabolism, the body being essentially an acid-producing organism—and this without becoming clinically alkalotic. In other words, the tendency of the allergic person is toward alkalosis rather than acidosis, though tests of blood, urine and alveolar air might not at all times definitely show this. In support of this contention I shall attempt to show that the more acidotic the patient is rendered, whether by one or other therapeutic measures, by intercurrent disease or by environmental change, the less allergic he becomes. The evidence is presumptive, indeed in some instances perhaps even fanciful, but its presentation may not be entirely unwarranted.

1. *Diabetes mellitus.* The diabetic individual is an acidotic individual, even though at all times he may not be showing ketone bodies in the urine; but it seems that he is rarely subject to the allergic diseases. Joslin[7] has encountered but 6 cases of asthma in more than 6,000 diabetic patients, and he states that Rackemann had never observed the coincidence of the two diseases until he sent him one case. Walker[8] reports that he has seen but two cases of diabetes among from 2,500 to 3,000 asthmatic patients.

2. *Starvation.* Several of the changes observed during starvation, even if only partial, are directly attributable to the acidosis that supervenes. According to my thesis it is this acidosis which caused the unprecedented decline in the allergic diseases among the citizenry of the Central Powers during their period of undernourishment in the latter years of the World War.

3. *Pregnancy.* It is a well known fact that allergic symptoms sometimes disappear entirely during the period of gestation, to reappear after the birth of the baby. It is equally well known that the alkali reserve is sometimes much lowered during pregnancy.

4. *Acute infectious diseases.* In the literature Duke,[9] Balyeat,[10] Pottenger[11] and doubtless others have commented on the fact that an acute bout of fever often entirely relieves allergic maladies for the time being; all practitioners of wide experience know that this is so.

[11] Pottenger, F. M., in discussion on Duke (footnote 9).

Concerning the changes in the body during fever, Macleod[12] writes as follows: "Since the general metabolism is increased, the excessive breakdown of the fatty substances, occurring as it does in the presence of a diminished combustion of carbohydrates, interferes with the proper oxidation of the fatty acid molecules and leads to the appearance of the so-called acidosis products in the urine, and consequently to a relative increase in urinary ammonia. A tendency to acidosis therefore exists. The acidosis may reach a considerable degree of severity and cause the tension of carbon dioxide in the alveolar air to become diminished." In short, during fever as acidosis seizes upon the organism the peculiar something called the allergic tendency loses its hold and recedes temporarily into the background.

5. *Sea voyage.* It is, of course, well known that persons whose asthma or hay-fever is caused by pollens can obtain complete surcease from their troubles by a trip to sea, where the air is practically pollen free, but the fact is not so often mentioned that many allergic persons not affected by pollens are also able to obtain this relief. I suggest that the explanation may be found in the studies of seasickness recently made by Oriel[13] of the Canadian Pacific Steamship Lines. Briefly summarized, his observations are as follows:

(*a*) Labyrinthine disturbances, if present, do not give rise to nystagmus or to alteration in labyrinthine tests. (*b*) Autosuggestion is not wholly responsible, as there is a distinct metabolic upset found in the prevomiting stage, which is shown by hyperglycemia followed by hypoglycemia, increased ammonia excretion, and the presence of acetone in the urine. (*c*) When vomiting is established there is a very severe acidosis, as indicated by the excretion of ammonia up to 265 mg. per hundred cubic centimeters and the presence of much acetone and diacetic acid in the urine.

(*d*) The administration of dextrose causes diuresis, abolition of acetonuria, and a fall in the ammonia excretion, resulting clinically in the relief of symptoms.

In seasick individuals, then, there is a very pronounced acidosis, and in voyagers not sick there is nevertheless a metabolic disturbance in the direction of acidosis. This acidotic factor in life at sea was long ago recognized by experienced ship's surgeons, who are wont empirically to advise passengers to eat exclusively of vegetables and fruits (i. e., substances with an alkaline ash) if they would avoid becoming sick.

6. *Sojourning at high altitude.* That nearly all allergic persons are free from attacks at altitudes of 4,000 feet or more is an established fact, usually explained by the relative freedom of the air from offending pollens; but how shall one explain the equal degree of relief obtained by individuals whose malady is not pollen-caused; and what to do with the recent interesting statement of Hurst[14] that sufferers sensitive to cats in the lowlands were not affected by cats in the highlands? Again I offer a metabolic rebalancing with a diminution in reserve alkali as the explanation. Henderson[15] has shown that as an adjustment to altitude the blood alkali of people in Colorado is normally lower than in inhabitants of the sea coast. The condition is not acidotic but acapnial; i. e., the loss of carbon dioxide through the augmentation of respiration is compensated by excretion of the excess alkali left in the blood; as a result, the individual does not become acidotic but he does lose alkali. In other words, patients sent to the Rockies or the Alps to obtain relief from asthma are being sent to regions where they undergo a depletion of alkali reserve.

7. *Asthma in the young.* In any of the acute maladies of the very young, acidosis is always to be feared for the reason that the balance is more easily tipped over toward the acid side in youngsters than in their elders. It is worthy of note that in the treatment of very young allergic patients any routine palliative measure is usually more effective than in grown children or adults.

8. *Gastric acidity and allergy.* Numerous observers have incidentally recorded the occurrence of achylia in allergy. Recently, Criep and McElroy[16] have made a deliberate study of the matter and report the presence of achlorhydria and hypo-acidity in a large percentage of allergic conditions. It is interesting to note also that in their studies of urticaria the Walzers[17] found that hive production was accelerated by hypochlorhydria and retarded by hyperchlorhydria. Now there is some disagreement among physiologists as to the exact mechanism of acid production in the stomach, but that the period of active secretion coincides with a period of lessened acidity of the blood is not a controversial matter so far as I am aware; during gastric secretion the acidity of the urine decreases. That is to say, in the normal person during gastric secretion the acid of the blood is drawn upon, but in the allergic person, in whom the supply of acid in the blood is not high because of the hypothetic increase in alkali reserve, there is sometimes hypochlorhydria or even achylia because the blood has so little acid-forming material to spare.

9. *Calcium therapy.* It has long been held that the calcium ion exerts a specific antipermeability effect on the tissues, but this notion has been dealt a severe blow by the studies of Tainter and VanDeventer.[18] Pottenger[19] feels that in allergy there is an overbalance of the parasympathetic nervous influences due in part to an excess of potassium as compared with calcium in the cells, and that, other things being equal, it should be possible to overcome this vagotonia by administering calcium. Now, as a matter of fact, calcium deficiency has not been uniformly found in allergy,[20] and it is apparent that the administration of calcium salts does not in all cases increase the calcium level in the blood.[21] Nevertheless, the administration of calcium salts sometimes causes improvement in any of the allergic diseases. In terms of the present hypothesis I would explain this by saying that calcium therapy is in effect acid therapy.

Haldane and his associates[22] have shown that the oral administration of large doses of calcium chloride increases the acidity of the urine, a large part of the calcium being converted into the relatively insoluble carbonates and phosphates, which are then lost in the feces; the liberated chlorine ion is absorbed and so increases the proportion of fixed acid in the body. Koehler[23] states that 15 Gm. of calcium chloride daily for eight days caused a drop in the carbon dioxide combining power of the blood from 51 to 35 per cent by volume. Howard and Clark[24] have substantiated his observations and have shown that in individuals with fever the efficiency of the drug in lowering the alkali reserve was increased; it is to be remembered that the febrile patient is relatively acidotic. Sollmann[25] says, in speaking of the state of calcium in the plasma: "The soluble and diffusible calcium exists mainly as calcium bicarbonate; and as the solubility of this is limited, the blood calcium cannot rise materially above the normal limit unless the acid-base balance is shifted toward the acid side." Therefore it would seem that whenever calcium is given and a rise in its level in the blood is actually obtained, this has been accomplished only by increasing the relative acidity of the medium. Roe and Kahn[26] have shown that calcium absorption is slower when the drug is given with food, which they explain as being due to the alkalinity of the intestinal tract. Calcium lactate, as well as calcium chloride, is probably also available for decreasing the alkali reserve, for some of it is probably converted into the chloride in the stomach; it has also been shown[27] to be more rapidly absorbed between meals when the intestinal tract is less alkaline, or when lactic acid fermentation within the tract is increased by the administration of large quantities of lactose.

10. *Whisky and acetylsalicylic acid.* Duke[28] has recently called attention to the value of this combination in asthma. He says: "If enough whisky is given them to make them sleepy and they are made to lie down and go to sleep, that is usually the end of the attack of asthma"; and of acetylsalicylic acid: "Several isolated papers on the usefulness of acetylsalicylate in the treatment of allergic conditions, especially asthma, have been rather sadly overlooked by the medical profession. The intelligent continued employment of acetylsalicylate continued through the night hours ranks second to very few symptomatic therapeutic agents at one's disposal at the present time." The effects of these two drugs are as follows:

Table 2.—*Relief Obtained by Desensitization in 2,185 Cases of Hay-Fever*

Authority	Number of Cases	Relief (in per Cent)			
		Complete	Marked	Slight	None

Average success (per cent)		70.5			
Average failure (per cent)				33.2	

Alcohol (*a*) slightly increases the absorption of the salicylates and (*b*) is quickly absorbed and more than 95 per cent oxidized to carbon dioxide and water, with acetic acid probably as an intermediate stage. This breakdown, which tends to increase the acidity of the tissues, begins in about five minutes but proceeds slowly, the combustion of 1 ounce (30 cc.) of whisky requiring about four hours for completion, during all of which time the acid side is being added to, as shown also by a relative increase in urinary ammonia.

Acetylsalicylic acid: It has long been suspected that the salicylates cause acidosis. Recently Johnson[29] carefully studied the subject and showed that therapeutic doses of either sodium salicylate or acetylsalicylic acid cause definite fixed-acid acidosis; i. e., a decrease in the alkali reserve of the blood with marked respiratory stimulation, so that the p_H remains unchanged. There is also produced an increase in lactic acid in the blood, which Hanzlik[30] is tentatively of the opinion is caused by a decreased functional efficiency of the kidney.

In short, whisky and acetylsalicylic acid cause relative acidosis.

11. *Mineral acid therapy.* For several years I[31] have been advocating the use of the following formula in the treatment of hay-fever:

		Gm. or Cc.	
℞	Nitrohydrochloric acid (*not* the dilute)	18	℥ ivss
	Water to make	120	℥ iv

Label: One teaspoonful in ⅔ glass of water, followed by another glass of water, after meals and again on retiring as near midnight as possible.

I am now able to report the results obtained in 237 cases by 34 physicians, each using the remedy in his practice for the first time, except my own 21 cases, some of which have been treated repeatedly for several years (table 1). Table 2 shows the results at present being obtained with desensitization methods. In table 3 the two methods are compared, and it is seen that the acid therapy is fully as effective as the desensitization.

Regarding the desensitization table, the figures here shown are admittedly high; i. e., they represent what is being accomplished by expert allergists and by no means by the general practitioner. Also they do not show the 2 or 3 per cent of patients who are actually made worse by the treatments,[32] or the 10 per cent who suffer constitutional reactions,[33] or the more than 50 per cent who have more or less severe local reactions. The treatments must, of course, be begun many weeks before the beginning of the season.

TABLE 3.—*Comparison of Results in Acid and Desensitization Treatment of Hay-Fever*

	Number of Cases	Complete Relief	Marked Relief	Successfully Treated (Marked plus Complete)	No Relief
Acid treatment....	237	37%	30%	67%	33%
Desensitization ...	2,185	19%	51%	70%	30%

As for acid therapy, it may be said that the treatment is begun only when the symptoms appear; there are no reactions; and the figures shown in the table probably represent the minimum that can be accomplished with the acid, for the reason that the amount required for different individuals must surely vary but these patients were all given the same dose, and also because no precautions were taken in any of these cases to guard against the taking of fruits and green vegetables whose alkali ash might completely combat the attempt to lower the alkali reserve with the acid.

SUGGESTIONS FOR FUTURE STUDY

1. Thorough chemical and physical studies of the blood and urine should be made in the large allergy services, with the object of determining the effect of all types of therapy, including desensitization, on the acid-base balance.

2. Ketogenic feeding should be instituted in a carefully controlled series of asthma and hay-fever cases.

3. A study of acid therapy should be undertaken on a large scale. Perhaps the best agents to use will be found to be U. S. P. dilute hydrochloric acid in large doses, ammonium chloride or sodium acid phosphate. I see no reason why nitrohydrochloric acid should be in any way superior to these more familiar substances. In any case the patients should be urged to eat freely of meats, fats and cereals, while green vegetables and fruits should be strictly forbidden because of their alkaline ash.

4. The effect on allergy of all other acidotic states, such as that occurring during exercise and as a part of the picture in severe chronic nephritis and in acute diarrhea, should be studied.

The State of Mind of an Infant.—One wonders at times what the state of mind of an infant must be when it finds itself most effusively and unhygienically kissed at one moment by the mother or strangers, and shortly after spanked because of unconscious attempts to exercise its arms or legs or lungs. A strangely inconsistent and unreliable world this must be to a baby, even though it knows nothing of the principles of hygiene or the laws of physiology. It is no wonder that James called this very youthful state of mind a "blooming confusion."—Swift, E. J.: The Psychology of Childhood, New York, D. Appleton & Co., 1930.

Clinical Notes, Suggestions and New Instruments

PIGMENTED MOLE OF THE SOLE OF THE FOOT RESULTING IN MELANOTIC SARCOMA

Arthur D. Kurtz, M.D., Philadelphia

This case is reported, not because of its rarity, but to draw attention again to a fatal ending of an apparently benign process.

REPORT OF CASE

Mrs. A. A., aged 54, white, a housewife, had always enjoyed good health. She weighed about 240 pounds (109 Kg.) and was 5 feet 5 inches (165 cm.) tall. She had never had any serious illness or been pregnant.

Sometime during the month of May, 1929, there developed on the sole of the left foot, about the middle of the arch, a small ulcer, which when first seen was about the size of a dime (18 mm. in diameter) and was surrounded by a pigmented border. It was treated once or twice by a chiropodist, who could not stop the spread of the ulcer; the patient was then referred to me. By this time the ulcer was about 1½ inches (38 mm.) in the transverse diameter and one-half inch (12 mm.) in the longitudinal diameter of the foot; there was a border varying in width from one-fourth to three-fourths inches (6 to 18 mm.) surrounding the ulcer. Early in July, 1929, the entire area was excised; only the skin was found involved and the operative wound healed quickly. The tissue was submitted for examination to Dr. J. H. Clark at the Samaritan Hospital; he returned a diagnosis of pigmented mole with no evidence of any malignant change.

The patient remained comfortable until early in March, 1930, when she felt as though she was walking on a marble. Examination showed a small hard mass in the scar from the previous operation. The mass was globular and about the size of an ordinary cherry.

Under a local anesthetic the tumor was removed; there was no appearance of infiltration of the deeper structures, the tumor peeling easily out from its bed. The entire bed was subjected to thorough fulguration, packed and dressed.

Within one week from the operation the upper lip swelled, became indurated and everted and apparently contained pus. On incision, free bleeding resulted, which caused considerable difficulty in stopping the hemorrhage.

About this time the report from Dr. Louis Tuft concerning the tumor removed showed it to be melanotic sarcoma, and the diagnosis of the lip involvement immediately became patent. It may be noted that the lip increased slowly in size, causing the upper front teeth to become loose and by its size interfered with eating and talking, until two weeks before death, when in an interval of thirty-six hours the swelling completely disappeared leaving a normally flat lip.

The patient was referred to Drs. J. H. Gibbon and W. W. Babcock, who concurred in the diagnosis. She was then referred to Dr. G. C. Bird for heavy dosage of x-rays. This was without any appreciable result, as growths began to appear all over the body and extremities. The scalp and face, except the lip, were not involved until two months ante mortem. The mode of appearance of the secondary growths was of interest: without warning or preliminary signs a black and blue area would appear; in from twenty-four to seventy-two hours a tumor varying in size from a pea to a baseball would make itself shown in the center of the discolored area, when the discoloration would fade, leaving the tumor mass. Some of the tumors would soften and ooze serum and blood.

In September, 1930, the patient's legs became markedly edematous and began oozing serum in several places where no growth was present. The heart showed gradual increase of rate with lowering of the muscle tone, the lungs gave bronchial breathing and in some places fine râles and an obstinate cough developed. October 1, severe pain involving both heels came on, following a week of increased appetite and a feeling of general well being. Twenty-four hours later she became delirious and on October 4 died. Autopsy was not obtainable.

There was little loss of weight during the illness; the patient was just as bulky to handle as when she was in good health. At the time of death there were six tumors in the scalp, two small ones on the forehead, and a large one that had apparently developed almost beneath the right zygoma and caused it to bulge outward. There was no opportunity to count the number on her body and extremities. At no time was there hematemesis, hemoptysis, hematuria or blood in the stools.

While it is known that metastasis in melanotic sarcoma is rapid, it would seem logical that walking on the growth before it was removed might have caused a more rapid spread from intermittent squeezing than would otherwise have occurred.

ACUTE HEMORRHAGIC PANCREATITIS: A CASE PRESENTING YELLOW DISCOLORATION AT THE UMBILICUS

Lloyd B. Johnston, M.D., Cincinnati

A moderately obese married woman, aged 37, whom I was asked to see after she had been ill for three days, gave a past history that indicated the presence of flatulence and eructation for four years. For two years preceding the present illness she had had increasingly frequent attacks of nausea, vomiting and upper right abdominal pain which radiated to the right scapular region and for which she was given morphine hypodermics on several occasions. Her present illness began with acute epigastric pain soon followed by nausea and vomiting early in the morning while she was in bed.

When I saw her she appeared very ill and was in marked distress one hour after the administration of a hypodermic dose of morphine. The temperature was 100.2 F., pulse 90, respiration 20. The body was warm but the hands were cold and clammy. There was no jaundice or cyanosis. Respirations were costal in type. The chest observations were negative. The abdomen was of a large type and moderately distended. There was a slight visible fulness of the epigastrium and upper right quadrant. At the umbilicus there was a 1½ inch circle of yellow discoloration resembling the yellow seen after the extravasation of blood or bile. There was a little generalized abdominal rigidity but in the gallbladder region and epigastrium there was extreme rigidity with exquisite tenderness. There was dulness to percussion over the upper right quadrant and to palpation an indefinite sense of a mass. The white blood cell count was 21,400 with 91 per cent of polymorphonuclear leukocytes. The urine contained albumin but no sugar. The preoperative diagnosis was perforation of a purulent gallbladder.

At operation the typical conditions of acute hemorrhagic pancreatitis were observed. There were from 1 to 1.5 liters of markedly blood-tinged peritoneal fluid, extensive fat necroses throughout the upper part of the abdomen and lesser peritoneal cavity, thickening of the base of the omentum, rounding of the liver edge, and thickening of the pancreas, especially of the head. The gallbladder was thickened and densely adherent. Palpation and scooping of the gallbladder, hurriedly done because of the patient's condition, did not reveal any stones. The gallbladder was drained with a soft rubber tube and several small soft cigaret drains were placed about it. The lesser peritoneal cavity was drained with several soft cigaret drains placed through the gastrocolic ligament, and the peritoneum over the pancreas was opened by blunt dissection.

The immediate postoperative condition was critical. The bile drainage lasted only two days, and after ten days several small faceted gallstones were discharged. After four weeks it was necessary, under gas anesthesia, to enlarge the tract into the lesser peritoneal cavity and place a soft rubber tube into it. At the same time the remaining gallbladder stones were removed, after which bile drained freely for several days. The drainage of foul pus and small sloughs from the lesser peritoneal cavity persisted for five weeks longer. Epigastric distress, cramplike epigastric pain radiating into the back, vomiting, anorexia and weakness characterized the patient's convalescence. Two blood transfusions were given. Marked improvement began about nine weeks following the first operation. At the end of four months the patient has been up and about for one month, she is free from pain, her appetite is good, and she is gaining daily in weight and strength. There is occasionally a little watery discharge from the drainage tract.

The immediate postoperative interpretation of the yellow umbilical discoloration was that it was due to the extravasation of pigments from the markedly blood-tinged peritoneal fluid, the color being the terminal blood pigment color change, namely, yellow, rather than blue or blue-green, which might have resulted from the presence of gross blood within the peritoneal cavity or from the digestion of tissues by pancreatic ferments. It is well known that blood or bile within the peritoneal cavity will extravasate its pigments to the surface at the umbilicus. Cullen[1] called attention to the blue umbilicus occurring after the rupture of an ectopic pregnancy. Ransohoff[2] described the yellow discoloration at the umbilicus observed in a case of rupture of the common bile duct.

In acute hemorrhagic pancreatitis, Halsted[3] was the first to describe the cyanosis which, according to Moynihan,[4] may be distributed irregularly over the surface of the abdomen or even of the limbs. In describing his case Halsted graphically represents the sign of cyanosis as "the white print of finger-tips in a slightly cyanosed field just over the site of greatest pain." This cyanosis has subsequently been observed by other writers and it is not to be confused with the type of discoloration being described in this report.

In a review of the literature it is not found that American writers have described true pigment discoloration of the abdominal wall in cases of hemorrhagic pancreatitis. It is described, however, by the English writers Cope,[5] Moynihan[4] and Bailey,[6] the latter two calling it "Grey Turner's sign." The three writers just mentioned do not cite cases of their own. G. Grey Turner[7] in his article describes two cases of acute hemorrhagic pancreatitis, one showing extensive umbilical discoloration and the other showing two large greenish discolored areas in the loins. The interesting description of his first case reads as follows: "In 1912 I was asked to see a big stout woman, 54 years of age, suffering from an acute abdominal illness of three days' duration. I was at once struck by the appearance of the abdominal wall surrounding the umbilicus. In this neighborhood there was an area of discoloration about 6 inches in diameter, of a bluish color, very like the postmortem staining seen over the abdominal wall or the appearance of the skin in a late case of extravasated urine. The area was slightly raised and pitted on pressure. In this case the patient suffered from acute pancreatitis. She lived nine days after operation and postmortem examination disclosed a sloughing pancreas with much fat necrosis." His second case, observed in 1917, was a late case showing two large greenish discolored areas in the loins, and the subsequent autopsy showed direct retroperitoneal extension of fluids from the sloughing pancreas to the loins.

Obviously the umbilical discoloration in Turner's case and the yellow discoloration in my case represent the same pathologic process. It is my opinion that the presence of the yellow discoloration merely represents the extravasation of blood pigments from the bloody peritoneal fluid. If the fluid were more bloody in type, blue or blue-green discoloration undoubtedly would occur. The marked discoloration and edema in Turner's case was probably also associated with some digestion of the tissues by pancreatic ferments. It is quite possible that in some late cases of acute hemorrhagic pancreatitis slight umbilical discoloration has been overlooked or disregarded. Dr. J. S. Spangler, resident surgeon at the Good Samaritan Hospital,

Cincinnati, has just informed me that he recently observed a small ring of yellow discoloration at the umbilicus in a patient who was not subjected to an operation and in whom the diagnosis of acute hemorrhagic pancreatitis was made at autopsy. It was not agreed by all concerned that the discoloration was real and his observation was not made a matter of record.

The case which I have reported demonstrates that yellow discoloration at the umbilicus may indicate the presence of acute hemorrhagic pancreatitis. As already described, yellow umbilical discoloration also may be present after rupture of the gallbladder or common duct. It is evident that umbilical discoloration in acute hemorrhagic pancreatitis can be present only in cases in which many hours have elapsed after the onset of the acute pathologic process.

COCCYGEAL HERNIA

Gustav A. Pagenstecher, M.D., San Antonio, Texas

Herniation of the abdominal viscera is found in every direction. The usual types of hernia are most frequently due to some congenital malformation or weakness.

Hernias through the pelvic floor are uncommon and are due in the main to mechanical injury after birth. In spite of the fact that the greater part of the hydrostatic pressure of the abdominal viscera is exerted on the pelvic floor, the strong but short pelvic fascia, aided by the sacrum, coccyx, pubic rami, sacrosciatic ligament, sacrotuberous ligament, urogenital ligament, levator ani and gluteus maximus muscles are able to hold the viscera back and prevent them from extruding through its vaginal and anal openings, making a hernia in this region one of the rarest of protrusions.

A woman, aged 50, came to me complaining of a pain in the region of the coccyx which was aggravated by sitting, coughing or straining at stool. This pain had been present since the birth of her only child twenty-seven years before.

Physical examination revealed a loose, tender, freely movable coccyx, which caused excruciating pain on manipulation. Otherwise laboratory and physical observations were negative.

A diagnosis of fracture with coccygodynia was made and I recommended surgical removal. She accepted the advice and the coccyx was removed by another surgeon.

Following this removal the wound failed to heal for about three months, all the while discharging a clear amber colored fluid which, from the description, resembled peritoneal fluid, and a large cavity was packed daily. This cavity gradually became smaller and finally healed.

With this history the patient reported to me a second time, about seven months after the removal of the coccyx, complaining of being unable "to sit down," that she had a "hernia," that she was "sitting on her bowels," and that she had to hold her bowels back when at stool.

The patient weighed 155 pounds (70 Kg.). In the region of the sacrum and coccyx was a rounded protruding mass which was freely movable and was easily replaced. Reducing the mass caused pain and discomfort. Coughing or straining brought the mass out. It was covered by a thin layer of healthy skin, was moderately firm, would gurgle when handled, and had all the earmarks of a hernia, about the size of an orange.

The triangular opening through which this hernia came was bounded above by the lower border of the sacrum and laterally by the gluteus maximus and levator ani muscles, and below it ran to a point at the anal orifice.

A finger in the rectum could be pushed in the hernial mass, which was separated from the examining finger by the skin over the posterior wall of the bowel.

OPERATION

With the patient in the prone position, a longitudinal, slightly curved, skin incision lateral to the hernial mass was made from the middle of the sacrum down to the anal orifice. The skin incision brought the rectum and terminal sigmoid into view. Gentle separation of a small mass of scar tissue permitted the posterior culdesac of the peritoneal cavity to be entered, allowing a view of the large bowel and small intestine. The sigmoid was mobile, but it was deemed inadvisable to fix it to the anterior surface of the sacrum at its regular mesenteric attachment. The peritoneum was freed and closed with interrupted plain catgut. The levator ani was next isolated and brought together in the midline with interrupted sutures of chromic catgut number 2. The remnant of the anococcygeal body was isolated and made fast to the lower edge of the coaptated levator ani muscles. This step was done with one finger in the rectum so that the anal orifice would not be occluded. Next, the edge of the pelvic fascia and the sacrotuberous ligament was sufficiently mobilized to be brought together in the midline.

To further strengthen this opening, the gluteus maximus muscle was mobilized from the subcutaneous tissue below and the gluteus medius anteriorly, and brought together in the midline, allowing a sufficient opening for the rectum and anus.

All muscle approximation was made with number 2, forty day double chromic catgut.

Four silkworm tension sutures were passed through the skin, gluteus maximus, levator ani muscles, pelvic fascia and peritoneum and tied over gauze sponges to hold successive layers together and prevent dead space.

The skin was closed with dermal interrupted sutures.

The patient was put to bed on her abdomen and kept there fourteen days. She was catheterized and the bowels were moved by colonic irrigations. She made an uneventful recovery. The hernia was absent after nine months had elapsed.

COMMENT

This hernioplasty was based on the same principle as any other hernia operation in other regions of the body; namely, approximation of muscles to muscles and fascia to fascia to occlude the hernial orifice.

What happened in this case was that a stout patient who had a very wide and deep pelvis had the anococcygeal body stripped from the sacral attachment during the removal of the coccyx.

No case of coccygeal hernia is on record in the present literature.

Medical Arts Building.

SUDDEN DEATH FOLLOWING THE INTRAVENOUS INJECTION OF BISMUTH TARTRATE

Stephen H. Curtis, M.D., Troy, N. Y.

As most of the reports in the literature on the use of bismuth in the treatment of syphilis are favorable, I thought that it might be of interest to report the unfavorable result obtained in this case.

REPORT OF CASE

W. H., aged 35, a mechanic, married, the father of three children, consulted me first in April, 1928, complaining of severe occipital headaches which had been persistent for five years and were relieved temporarily only by taking large quantities of acetanilid preparations. Associated with this was a marked loss of ambition and feeling of languor. His personal history, prior to the onset of the headaches, was negative. He stated that he had not had venereal infection, although at a later date he admitted the occurrence of a chancre twenty years previously. The patient was rather tall, was somewhat emaciated, and had sparse gray hair. His appearance was that of a man of 50. His skin was pale, with a somewhat bluish hue. The teeth were poor and many were missing. The throat appeared normal. The pupillary reflexes were present. The lungs were normal; the heart sounds were clear and slow, 70 beats a minute. There were no irregularities nor adventitious sounds. The blood pressure was 110 systolic and 68 diastolic. The abdominal examination revealed nothing remarkable. There was no evidence of any adenopathy. The knee jerks were present and active. There was no evidence of a Romberg sign. The urinalysis was negative. The blood examination showed a hemoglobin of 70 per cent; red cells, 3,250,000; white cells, 6,200. The smears showed some anisocytosis and a definite achromia. The blood Wassermann reaction was four plus positive with both the alcoholic and the cholesterolized antigens.

Intensive antisyphilitic treatment was begun. Yellow mercuous iodide in one-fourth grain (0.016 Gm.) doses were administered three times daily; 0.6 Gm. of sulpharsphenamine was given intravenously at weekly intervals for ten weeks. There was a complete cessation of the headaches after the third week and a marked improvement in his physical condition. This was followed by ten weekly injections of mercurosal,[1] 0.1 Gm., intravenously. For a period of one month all treatment was stopped. At the end of the month the Wassermann reaction remained four plus positive. The same treatment was repeated for another twenty weeks with a month's rest at the end, when the Wassermann reaction was still four plus positive. There had been no recurrence of symptoms and the improvement had been progressive. For a period of three months no treatment was given.

In October, 1929, the patient reported for examination. He had no complaints and his appearance was good. The blood Wassermann reaction was still four plus positive. He was suspected of being "Wassermann fast" and advised to continue for another three months' period without treatment.

His physical condition had remained the same and so had the Wassermann, four plus positive. In January, 1930, I discussed the condition frankly with the patient, pointing out that while the Wassermann reaction had remained persistently positive he had no evidence of syphilitic activity. Nevertheless, he was not satisfied with the blood remaining positive.

I suggested the intravenous use of bismuth, to which he promptly agreed. Subsequently a course of ten doses of 15 mg. each of bismuth tartrate suspended in 5 cc. of sterile distilled water was given intravenously at weekly intervals. It is interesting to note that within half an hour after the administration of each dose the patient was seized with abdominal pain resulting in one or two watery stools, after which the reaction promptly disappeared and the patient felt quite normal again. The Wassermann test performed one month later showed a plus minus reaction with the plain alcoholic antigen and a two plus positive with the cholesterolized antigen. This was the first change that had been shown in the Wassermann reaction since the initial test before any treatment had been given. The patient was advised to suspend treatment for another month, at the end of which time the Wassermann reaction remained the same as on the previous test.

In June, 1930, another course of bismuth was decided on. The usual dose of 15 mg. of bismuth tartrate suspended in 5 cc. of sterile distilled water was administered intravenously. Immediately the patient became pale and cyanosed, remarked that everything was getting black, and lapsed into unconsciousness. The breathing became stuporous and labored, then slow and irregular. There was no pulse perceptible at the wrist. The heart was slow and very feeble. The blood pressure was so low as to be impossible to record. One cubic centimeter of epinephrine hydrochloride was administered directly into the ventricular wall. There was no response. The patient had died. This all took place within a period of less than five minutes. There had apparently been a complete vasomotor failure.

Prior to the administration of this last dose of bismuth, the patient had completed his usual day's work and had expressed himself as "feeling fine." It appears to me that this dose of bismuth had produced a sudden paralysis of the vasomotor system resulting in a complete collapse.

COMMENT

I have used bismuth with the same technic in ten other so-called Wassermann fast cases, eight of which showed reactions to a lesser degree and two were completely negative in the Wassermann test. In none of these cases has there been any manifestation of a reaction whatever, systematically. This patient may have had an idiosyncrasy toward bismuth although the only suggestion of it in ten doses given previously had been the slight intestinal disturbance. The size of the doses had all been the same and there had been an interval of one month with no treatment between the tenth and the last dose.

Unfortunately, a necropsy was not obtainable.

80 First Street.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. Puckner, Secretary.

DEXTROSE (See New and Nonofficial Remedies, 1930, p. 245).

The following dosage forms have been accepted:

Ampoule Sterile Solution Dextrose, U. S. P., 5 Gm., 10 cc.: Each ampule contains dextrose, U. S. P., 5 Gm., in distilled water to make 10 cc.

Prepared by the E. S. Miller Laboratories, Inc., Los Angeles.

Ampoule Sterile Solution Dextrose, U. S. P., 10 Gm., 20 cc.: Each ampule contains dextrose, U. S. P., 10 Gm., in distilled water to make 20 cc.

Prepared by the E. S. Miller Laboratories, Inc., Los Angeles.

Ampoule Sterile Solution Dextrose, U. S. P., 25 Gm., 50 cc.: Each ampule contains dextrose, U. S. P., 25 Gm., in distilled water to make 50 cc.

Prepared by the E. S. Miller Laboratories, Inc., Los Angeles.

Dextrose (d-Glucose) Unbuffered and Without Preservative, 10 Gm., 20 cc. Ampul: Each ampule contains dextrose, U. S. P., 10 Gm., in distilled water to make 20 cc.

Prepared by the H. K. Mulford Co., Philadelphia.

Dextrose (d-Glucose) Unbuffered and Without Preservative, 25 Gm., 50 cc. Ampul: Each ampule contains dextrose, U. S. P., 25 Gm., in distilled water to make 50 cc.; accompanied by an ampule of 2 cc. of a buffer solution, each cubic centimeter containing disodium hydrogen phosphate ($Na_2HPO_4.2\,H_2O$) 0.0745 Gm. and potassium biphosphate (KH_2PO_4) 0.0122 Gm.

Prepared by the H. K. Mulford Co., Philadelphia.

Dextrose (d-Glucose) Unbuffered and Without Preservative, 25 Gm., 50 cc. Double End Vial: Each double end vial contains dextrose, U. S. P., 25 Gm., in distilled water to make 50 cc.; accompanied by an ampule of 2 cc. of a buffer solution, each cubic centimeter containing disodium hydrogen phosphate ($Na_2HPO_4.2\,H_2O$) 0.0745 Gm. and potassium biphosphate (KH_2PO_4) 0.0122 Gm.

Prepared by the H. K. Mulford Co., Philadelphia.

Dextrose (d-Glucose) Unbuffered and Without Preservative, 50 Gm., 100 cc. Ampul: Each ampule contains dextrose, U. S. P., 50 Gm., in distilled water to make 100 cc.; accompanied by an ampule of 4 cc. of a buffer solution each cubic centimeter containing disodium hydrogen phosphate ($Na_2HPO_4.2\,H_2O$) 0.0745 Gm. and potassium biphosphate (KH_2PO_4) 0.0122 Gm.

Prepared by the H. K. Mulford Co., Philadelphia.

VENTRICULIN.—Desiccated, defatted, hog stomach.—It is assayed clinically by observation of the reticulocyte response, the standard being an increase of red blood cells at the rate of about one hundred thousand cells per cubic millimeter per week when the product is administered to patients suffering from pernicious anemia.

Actions and Uses.—Stomach tissue of animals has been shown to contain a principle capable of stimulating the bone marrow to form immature red cells (reticulocytes) in large numbers during the first ten to fifteen days of its oral administration (Sturgis and Isaacs, The Journal, Sept. 7, 1929; Sharp, ibid.). The reticulocyte production reaches a peak at some point during this initial period of treatment from seven to twelve days—after which a recession takes place and normal red blood cells appear in the blood stream in greatly increased numbers. Hemoglobin and thrombocytes gradually attain their normal relation to the red blood cells with adequate doses. In the treatment of pernicious anemia the daily reticulocyte count is the best method of detecting improvement in the patient during the first two weeks. When, during the first ten to fifteen days' treatment with ventriculin, a satisfactory rise in reticulocytes occurs, this is evidence that effective and progressive blood regeneration is taking place.

Dosage.—The administration of ventriculin may be instituted on a conclusive diagnosis of primary anemia: from 20 to 30 Gm. (2 to 3 vials) are administered daily, suspended in a half-glassful of water or fruit juice. When the red blood cell count has reached a satisfactory level, 10 Gm. (1 vial) is sufficient as a maintenance dose. In severe relapses a dosage of from 20 to 30 Gm. (2 to 3 vials) is indicated.

Manufactured by Parke, Davis & Co., Detroit. U. S. patent applied for. U. S. trademark number 270,811.

Ventriculin is a granular substance, practically insoluble in water and having a faint odor and slight taste.

To prepare ventriculin, fresh, whole stomachs from healthy hogs are freed from extraneous fat, ground and dried in a vacuum at a temperature not exceeding 65 C. The dried material is then defatted by extraction with purified benzine. The defatted material is dried without further application of heat, ground and milled to coarse powder. A representative sample of each lot is tested on known cases of pernicious anemia under the supervision of the Henry Simpson Memorial Institute, University of Michigan, Ann Arbor, Mich. No product is released for use until approved by the Simpson Memorial Institute.

MICROBIC DISSOCIATION

Changes in morphology and biologic characteristics of bacteria have recently been the subject of controversy among bacteriologists. Hadley,[1] in a monograph entitled "Microbic Dissociation," has comprehensively reviewed the investigations in this field. In 1877 Nägeli,[2] representing the prevalent opinions of the time, declared in his "Lehrbuch" that fission fungi came from a single type of cell which appeared in diverse forms and possessed a variety of biologic characteristics. About the same time Cohn [3] presented a system of bacterial differentiation based solely on morphology and biologic characteristics. This specificity of bacteria was passed on by Koch and was generally accepted as law until the past decade, although Neisser [4] in 1906, Massini [5] in 1907 and a few others showed that some bacteria may change both form and activities. Hadley found that many observations of bacterial changes made during the course of other studies and reported in the literature were generally regarded by observers as contaminants. Only in recent years have bacteriologists openly considered the possibility of anything more than minor changes in the form of bacteria. They have now begun to attack the problem seriously and much is being written.

Two main schools of thought dominate the question. The radicals Löhnis, Mellon and Enderlein, three of the leading proponents, maintain that complete changes in form and character may take place. Mellon [6] claims that he has been able to transform diphtheroids into various other organisms, including streptococci. Later he [7] found that involution forms could be made to grow under proper conditions. His work led him to conclude, as did Enderlein [8] and Löhnis,[9] that these forms may represent part of a sexual cycle which bacteria undergo. Mellon believes that bacteria can be regarded as "fungi imperfecti." True, his work is only just now being regarded seriously. The conservative group, to which most bacteriologists belong, maintain that almost all organisms can show variant forms under proper conditions, but they have not entirely accepted the views of Mellon. They are content with describing two main forms of each organism, the S, or "normal," and the R, or mutant, form. They regard the S type as growing fairly well on agar, the colonies generally being smooth and small, capsulated, active in motile species, and representing the "normal" morphology, while the R form generally grows expansively on agar, and the colonies are rough, irregular and flat, are nonmotile in the motile species, and have a tendency to form short rods and cocci. They contend that the R form is more common in convalescents, in carriers and in chronic diseases, and is more resistant to aging and to bacteriophage. They declare that the R form is more susceptible to phagocytosis, while serum against S may force the "normal" S into the R form. This last may explain the action of immune serum in certain diseases. Hadley declares that in the dissociative process the R form is an indirect rather than a direct product of the S form. He finds that the basic factor which incites dissociative reactions is any condition unfavorable to the growth of the S type. He cites evidence indicating that virulence is not evenly distributed through all stages of growth but is commonly restricted to the S form. He believes that the increase of virulence is dependent on the increase of the S over the R form. It has been determined that profound serologic changes take place in the transformation of the S to the R type and that there is not only a loss of old antigenic power but also a gain of new antigenic substance. Hadley believes that the frequent serologic discrepancies observed are due to dissociative reactions. He cites investigations showing that only certain stages of organisms possess immunizing power. He warns against the possibility that organisms, if taken into the body, may by dissociation become virulent. He suggests also that the so-called filtrable virus may represent an ultramicroscopic and virulent dissociate of some common unsuspected avirulent organism. Marked changes in the tubercle bacillus have been found by many workers, one stage of the cycle being a filtrable virus. Ninni [10] was able to isolate acid fast organisms from the lymph glands of animals injected with the filtrate of tubercle bacilli. Hadley believes that the rickettsia bodies will be explained on the basis of microbic dissociation. Investigators find that the reversion of R back to the S form does not take place with the ease with which the S becomes the R form, and because of this some hold that there is a true mutation from S to R and that R represents a new organism. Hadley believes that it is

premature to accept this phenomenon as a mutation until all possible changes in environment have been tried. He suggests that the word mutation be kept out of the vocabulary of bacteriologists until all organisms have been studied to the fullest to determine all possible changes an organism can undergo. He[11] cites evidence which leads him to believe that bacteriophage is part of dissociation and that lytic areas represent transitory secondary colonies, which in turn form tertiary colonies. Bordet and d'Herelle regard these tertiary colonies as resistant secondary colonies.

The revolutionary advances made in the study of microbic dissociation in the past decade are not generally known to clinicians. It would seem as if the clinician must wait for the bacteriologist to define the limits of variability of various organisms, the relationship of one organism to another and the changes if any that are incited in an organism by the host, before attempts to advance therapeutically can be made. Studies in microbic dissociation may clear up many ill defined clinical relationships between various organisms: whether the colon-typhoid group comes from a common ancestor, whether under certain conditions they are transformed from one type of organism into another, and why *Streptococcus scarlatinae* will sometimes produce only sore throats in the experimental production of scarlet fever. Enderlein as well as Hadley has suggested that therapeutic endeavor in the future may not be concerned with the attempt to kill organisms in the body but to try to force them into a nonvirulent stage. It would seem that the teaching of bacteriology in the future must point out the possibilities in this field. Mellon's contention that bacterial changes represent part of a sexual cycle would seem logical since all other types of life show this phenomenon. Perhaps, as Hadley has suggested, out of the confusion of rods changing to cocci will be evolved new laws to show that these changes follow a logical order.

HUMAN MILK FLOW

Despite the advances that have been made in recent decades in the practical aspects of the artificial feeding of infants, pediatric advice still stresses the preference for breast milk whenever conditions make its use possible. When Mrs. Rose[12] wrote "Happy the baby who enjoys his inalienable right to Nature's food supply—his own mother's milk!" she added that his chances of a long and healthy life are immensely greater than those of the unfortunate child who has to be artificially fed. In case of misfortune depriving him of his natural food supply, the best substitute is the milk of some other healthy woman with a baby of approximately the same age. Indeed, the breast-fed baby has a better chance not only of surviving the perilous first year but of growing to manhood as well.

Even the partial acceptance of such views makes it imperative to devote much attention to the problems of human milk flow—a subject that has received far less scientific study than it obviously deserves, owing to indifference and misguided sentiment. It has been pointed out that many rational theories have been advanced on the subject but that it is not known whether nervous, chemical or glandular agents operate to start the flow of milk.[13] Even seemingly convincing experimental evidence is contradictory concerning the causes of the hypertrophy of the mammary glands during pregnancy and their secretory activity immediately after parturition. There is a general opinion that nervous shock, certain psychic states caused by the presence or absence of the suckling reflex, and the emotional status and environment of the mother affect the flow of milk. The limitations of our knowledge are further indicated by the reminder that the increased circulation of blood after the discharge of the fetus has been considered to be one factor in the initiation and continuation of milk flow, while the presence in the blood of particular chemical excitants that favor milk formation is another.[13] The evidence concerning the influence of chemical excitants in the blood is, we are told, the more convincing, but it is impossible to say whether these hormones or galactagogues have their source in the placenta, in the fetus or in certain glands of internal secretion.

The elaborate investigation of Macy and her collaborators at the Children's Hospital of Michigan in Detroit have disposed of at least one debated feature of human lactation. As part of the activities of a mother's milk bureau, the routine technic consisted in securing the entire production through expression of the milk from the breasts. In most earlier studies the records for milk yield have been secured by weighing the babies before and after nursing and quantitatively expressing the remainder of the milk. In the Detroit studies the suckling stimulus was entirely absent after the first few days post partum, since the babies were not allowed to nurse. The total milk supply was expressed by hand, the babies receiving their own mothers' milk by bottle. That is, the psychic effect of the suckling reflex of the child did not influence the types of milk production curves obtained in this investigation. Nevertheless, large yields of milk were secured over long periods. For example, the average daily output of milk from the sixth week through the fourteenth month was 2,602 cc. for one mother in her first lactation period and 3,134 cc. in her second; 2,366 cc. for another person, and 1,419 cc. for a third. These are substantial yields even though they do not approach Kollmann's[14] record of a woman who produced as much as 5,950 Gm. of milk in one day and was able to nurse from one to seven babies throughout fifty-one weeks of lactation. Evidently the suckling reflex of the child is not necessary for the stimulation and continuance of heavy milk flow in all women.

The Detroit studies confirm the evidence that there are significant variations in the volume output of milk of individual women from hour to hour and from day to day. Such fluctuations, we are assured, may have an appreciable influence on the nurturing of the average breast-fed infant. There is a definite individual functional capacity for producing milk at a given time in the lactation period. It has repeatedly been stated that within limits the quantity of milk secreted by physiologically normal mammary glands adjusts itself to the demand. The removal of milk from the breasts encourages secretion, whereas the accumulation of milk discourages it. When a greater demand is placed on the mammary glands, the quantity of milk output is increased.[15] The Detroit observations show that frequent and thorough stripping of the breasts seems to be effective in producing notable increases in the output of milk at any stage of lactation. This is important for the increasing number of lactating women who are disposing of surplus milk in the modern milk bureaus.

HEXYLRESORCINOL AS AN ASCARICIDE

Among the larger intestinal parasites of man, the attention paid in medicine to all the roundworms other than the hookworm seems to be relatively slight. This is particularly true of the eelworm, *Ascaris,* undoubtedly the most important of the lesser group. Ascariasis in man is not a rarity. The eelworms are among the most frequent human parasites. According to Chandler [16] they occur in all parts of the world and are found, especially in children, in the majority of temperate countries, even in countries as far north as Greenland and Finland. In the tropics they are abundant and are almost universally present in children, each individual harboring anywhere from two or three to several hundred worms.

Even though *Ascaris* does not have the reputation of being a particularly dangerous invader, it doubtless shares with other intestinal worms the menace of affording an unsuspected portal of entry to bacteria and protozoa. Chandler has recalled the admonition of Shipley that the intestinal worms play a part within our bodies similar to that played by blood-sucking arthropods on our skins, except that they are more dangerous since, after all, only a relatively small percentage of biting insects have their probosces soiled by organisms pathogenic to man, whereas the intestinal worms are constantly accompanied by bacteria, such as *Bacillus coli,* which are capable of becoming pathogenic if they gain access to the deeper tissues, as they are able to do through the injuries made by parasitic worms.

The traditional drug for expelling *Ascaris* has been santonin, though more recently the oil of chenopodium has come into vogue. The problem of an effective vermifuge is complicated by many factors. Foremost is freedom from danger of toxicity to the host. Another essential is that the worms shall actually be killed, not merely anesthetized or irritated so that they migrate within the body and produce more serious invasions of tissues. Strangely enough, intestinal parasites are somewhat variable in their reactions to drugs. According to Lamson, Minot and Robbins,[17] carbon tetrachloride and tetrachlorethylene, which are both efficient against hookworm, are relatively ineffective against ascarids and may cause dangerous migration of these parasites. Occasional deaths have followed the classic vermifuges. Lamson, Ward and Brown,[18] working at Vanderbilt University School of Medicine in Nashville under the auspices of the International Health Division of the Rockefeller Foundation, believe that they have discovered an effective and safe ascaricide in hexylresorcinol. This drug possesses marked germicidal properties and is employed for the treatment of urinary infections. According to New and Nonofficial Remedies,[19] the drug appears to be efficient against infections due to *Streptococcus anhemolyticus* and *Bacillus pyocyaneus,* but to be less efficient in the treatment of infections due to *Bacillus coli.* Hexylresorcinol is stated to be relatively nontoxic when administered by mouth. It is excreted by the kidneys, being largely decomposed but imparting definite germicidal properties to the urine.

Hexylresorcinol has irritant properties. They are not regarded as a contraindication for its occasional use and they are transitory in effect. The Nashville pharmacologists feel justified, after extensive preliminary studies on animals and man, in suggesting crystalline hexylresorcinol as an ascaricide in spite of its irritant properties, because they feel that it is exceptionally effective; it kills rather than anesthetizes the parasites, thus reducing the danger of migration; its irritant action, which should theoretically be merely superficial, has been shown by experiment to be so; and, finally, because hundreds of patients have taken this substance in olive oil solution as a urinary antiseptic in much greater amounts than is suggested for ascariasis without known complications. When given as an ascaricide, it should be taken on an empty stomach to prevent the possibility of its combination with the proteins of the food. Lamson and his co-workers record the general belief that one must have a vermifuge that will remove all the worms in a single dose. This is important when elaborate preparations for treatment must be made and when there is danger of intoxication. If, however, as is the case with hexylresorcinol, no preparation of the patient is necessary except to take the drug in the morning on an empty stomach and to wait an hour or so before eating to let the drug come in better contact with the parasites, there is no reason, according to Lamson, Ward and Brown, why the drug should not be repeated if necessary. Therapeutic research of this character obviously requires confirmation on a large scale for final acceptance.

Current Comment

SECRETION OF ALIEN PROTEINS IN HUMAN MILK

Infants fed exclusively on breast milk at times develop eczema, urticaria, asthma and other anaphylactic symptoms. The withdrawal of certain articles of food from the mother's diet often leads to cessation of these symptoms, eggs being the most common exciting agent. In a few cases skin tests have been made showing the infant's hypersensitivity to maternal milk, but attempts to identify the allergic excitant in this milk have thus far given negative results. Stuart, for example, in 1923, could not demonstrate egg proteins in apparently toxic human milk by the most delicate anaphylactic method at his command. Pediatricians, therefore, have been forced to consider the possibility that the toxic agent is some individual metabolic or secretory abnormality in human milk, the egg diet being responsible for this maternal biochemical perversion. Since Stuart's publication, however, newer and more delicate methods of allergic research have been introduced, particularly the method of local protein assay championed by Coca and Grove.[1] In the Coca-Grove test, 0.1 cc. of human [sic] anti-egg serum is injected intradermally into a dozen or more widely separated skin sites in a normal individual. Forty-eight hours later, graded doses of highly dilute egg white are injected into the same areas. Positive local skin reactions are at times demonstrable with egg dilutions as high as 1 : 1,000,000,000, a specific protein test a thousand times more delicate than the sensitization test of guinea-pig anaphylaxis. Applying this quantitative technic to human milk, Dr. H. H. Donnally,[2] of the Department of Pediatrics, George Washington University, currently reports that after an egg diet normal human whey often contains as much as one part in a million of apparently unaltered egg white. This represents in the neighborhood of a milligram of egg protein in each daily infant feeding, an amount fully sufficient to account for allergic symptoms. If Donnally's work is confirmed and found equally applicable to other food proteins, there is no necessity of assuming metabolic or secretory abnormalities in nursing mothers in order to account for occasional eczemas, urticarias and other food allergies in breast-fed infants.

COMPOSITION OF AQUEOUS HUMOR

Before practical use can be made of scientific data, the available facts must be established and classified. The great value of biochemical analyses in medicine at present lies in the enormous mass of information on the normal organism on which is established a base line from which the deviations are determined and interpreted. The recent report of Krause and Yudkin[1] on the composition of the aqueous humor of the eye emphasizes the fact that few tissues and fluids of the body have escaped investigation by the biochemist. These investigators point out that the make-up of the aqueous humor of the dog is in general similar to that of the ox, pig and horse and also to the dialysate of blood serum. Furthermore, a comparison of the composition of the spinal fluid and aqueous humor on the basis of determinations of a relatively few constituents leads to the conclusion that the two fluids have practically the same constitution. The composition of cerebrospinal fluid in turn closely approximates that of the plasma except for the protein. These studies indicate that under normal conditions the fluid in the anterior chamber of the eye is essentially in chemical equilibrium with the plasma, the nonprotein constituents passing more or less freely through the limiting membranes of the blood vessels, and a definite ratio existing between the concentrations in the plasma and in the aqueous humor. A similar conclusion has been reached by Arnold and Mendel[2] with reference to the relative compositions of blood and lymph. The studies on the ocular fluid indicate that its function is physical and nutritive. Its physiologic value does not lie in peculiar chemical activity such as is the case, for instance, in the gastric juice.

VIOSTEROL

It has repeatedly been established that the product resulting from the irradiation of ergosterol with ultraviolet rays may give rise to toxic manifestations when enormous doses are administered. Such amounts represent many hundred times those that bring about cures of rickets.[3] Although the chemical nature of ergosterol is well established, the nature of its irradiation derivatives or isomers that constitute the equivalent of vitamin D remains to be elucidated. The phenomena that have been described as hypervitaminosis with vitamin D are varied in character. Hypercalcemia is a prominent symptom; and it can be produced in parathyroidectomized animals, thus showing that in all probability the antirachitic factor does not act through the intermediation of the parathyroid glands.[4] Holtz and Schreiber[5] of Göttingen have recently reached the conclusion that irradiation of ergosterol produces a number of distinct substances. One is the antirachitic factor, perhaps vitamin D proper; another is a separate component producing calcification and designated by Heubner as the "calcinose" factor. The two effects, antirachitic and toxic, can be separated; or at least one can be destroyed while the other remains intact. If these observations prove to be correct, they may lead to a desirable purification of viosterol so as to eliminate or diminish the "toxic" features of its action.

Association News

THE PHILADELPHIA SESSION

Scientific Exhibit: Announcement of Exhibit by Section on Radiology

The Section on Radiology has appointed the following members as the Committee on Section Exhibit: Byron H. Jackson, M.D., Scranton, Pa.; Eugene P. Pendergrass, M.D., Philadelphia, and Henry K. Pancoast, M.D., Philadelphia, chairman.

The committee again points out that one of the functions of the Section on Radiology is to cooperate in educational matters. One of the ways in which this educational program can be fostered is by the members of the Section on Radiology arranging a well selected exhibit for the Philadelphia Session. The committee, therefore, invites applications for exhibits of investigative character dealing with the subject of radiology.

The radiologic exhibit may be in the form of original films or reduced transparencies. Prints, provided they are suitably mounted on cardboard, are also desirable. In cases of transparencies or of prints, emphasis should be placed on the use of amply printed explanatory legends; a third dimensional exhibit correlating the films is particularly impressive. As in the case of all exhibits, personal demonstration is required.

The section exhibit of the roentgenograms may be used to illustrate subjects dealt with in papers read before the section.

The Committee on Scientific Exhibit has made arrangements to furnish illuminating boxes for the display of films.

Members of this specialty are requested to take inventory of materials that might illustrate phases of radiology and communicate with the committee chairman, Dr. Henry K. Pancoast, X-Ray Laboratory, University Hospital, Philadelphia, Pa. All applications must be made on the regular application form, which is the one required by the A. M. A. Committee on Scientific Exhibit. A circular letter giving information concerning this exhibit, together with the usual application blank, will be mailed to those who have registered in the section during the last three years. Those who have not registered in this section but who are interested in such an exhibit may obtain a circular letter and application blank by sending the request to Dr. Pancoast. Applications should be filed not later than Feb. 10, 1931, with Dr. Pancoast.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10:15 on Tuesday, 10:30 on Thursday and 10 on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

November 24. Rural Health Work.
November 25. Mental Hygiene—An Important Public Health Problem.
November 29. Preventing Disease of the Teeth and Gums.

Five Minute Health Talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

November 24. How's the Baby?
November 25. What's Clean or Unclean?
November 26. The Sore Throat Danger Signal.
November 28. How's the Baby?
November 29. Wash Your Hands.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Licenses Suspended and Revoked.—At the meeting of the California State Board of Medical Examiners in Sacramento, October 21-22, the licenses of the following physicians were disposed of as follows:

Dr. Robert H. MacLauchlan, San Francisco, suspended for one year for hiding and abetting an unlicensed practitioner.
Dr. John R. Leadsworth, Los Angeles, suspended for one year for aiding and abetting an unlicensed practitioner.
Dr. Clarence E. Edwords, San Francisco, revoked, following an illegal operation.
Dr. Walter C. Hoyt, Gridley, revoked for habitual intemperance.
Dr. Thomas O. Greig, Berkeley, placed on probation for five years without a federal alcohol permit.

University News.—Among the recent gifts to the University of California were $10,000 from J. H. Mackenzie, San Francisco, for the investigation and treatment of diseases of the nervous system; $5,000, anonymously, for the support of investigations on infantile paralysis in the Hooper Foundation; $2,000 from the estate of John Fryer and from his sons and daughters to establish a John Fryer Chinese Library Fund; $2,500 from Dudley Cates, for research in neurologic surgery, and $1,000 from the National Canners' Association toward the salary of Prof. J. C. Geiger of the Hooper Foundation.——At the semiannual alumni day of the University of California Medical School, San Francisco, November 21, Dr. Harold Brunn, among others, spoke on "Newer Treatment of Atelectasis"; Dr. Howard W. Stephens, "Injuries of the Chest"; Dr. George K. Rhodes, "Spinal Anesthesia," and Dr. Harry M. Blackfield, "Skeletal Immobilization of Fractures of the Leg."

CONNECTICUT

Health Surveys of Cities.—Health surveys are being conducted by the Yale University School of Medicine in four cities and towns, namely, Winsted, Stratford, West Hartford and Haddam, at the request of each community. Public health inventories have already been made in Greenwich, North Haven, Westport, Middletown, Hartford, Ansonia, New Haven, Hamden, Manchester and Danbury. Under the terms of its endowment, the department of public health at the Yale University is charged with the obligation to promote the general cause of public health in the state and is subject to service calls from any community in making a survey and inaugurating improvement measures needed. The services are free, but to insure successful conclusions the department requires that the community shall cooperate in forming a permanent advisory committee in carrying out the recommendations of the survey and that the community pay traveling expenses of the staff and the cost of printing reports. The work is done with the full cooperation of the state health agencies.

GEORGIA

Society News.—"Trichomonas Vaginalis and Vaginitis" was the subject of a paper by Dr. Walter R. Holmes, Jr., delivered before the Fulton County Medical Society, Atlanta, November 6, and Dr. Claude S. Beck, Cleveland, spoke on "Pneumocardiac Tamponade in Relation to Pneumothorax." ——The Burke County Medical Society was addressed, November 6, by Dr. James M. Byne, Jr., Augusta, on "Coronary Thrombosis."

ILLINOIS

Society News.—The Rock Island County Medical Society was addressed, November 11, by Dr. George de Tarnowsky, Chicago, on "Surgical Management of Carcinoma of the Colon." ——Dr. Hugh A. McGuigan, Chicago, addressed the Grundy County Medical Society, November 12, on "Digitalis Therapy."——Dr. Stanley S. Burns, St. Louis, addressed the Williamson County Medical Society at Marion, November 18, on "Diagnosis and the Importance of Focal Infection in the Nose and Throat."——Dr. Lesley E. Wallace, Thebes, addressed the Alexander County Medical Society at Cairo, October 18, on "Coronary Thrombosis." ——"Arterial Hypertension" was the subject of Dr. Frank Buckmaster, Effingham, before the Effingham County Medical Society, October 30.

Chicago

Society News.—The Chicago Roentgen Society was addressed, November 12, by Drs. Henry W. Meyerding, Rochester, Minn., on "Bone Tumors"; Adolph Hartung, "Fibrocystic Disease"; Fremont T. A. Chandler, "Lesions of the Isthmus of the Lower Lumbar Vertebra," and Dallas B. Phemister, "Roentgen Changes in the Head of the Femur in Intracapsular Fractures."——Dr. Harry J. Corper, Denver, addressed the Chicago Tuberculosis Society, November 13, on "The Tubercle Bacillus—Experimental Studies."——Among others, Dr. Arthur Weil addressed the Chicago Pathological Society, November 10, on "Silver Impregnation of Gliomas with Davenport's Method."——Dr. Ramon Castroviejo gave a demonstration of clinical cases; scheme of diplopia; demonstration of Lacarrere's diaphragm of double slit before the Chicago Ophthalmological Society, November 17. Hugo Fisher, D.D.S., Drs. Castroviejo, Edward White and Willis S. Lemon, Rochester, Minn., conducted a symposium on the etiology of uveitis.——Dr. John B. Deaver, Philadelphia, addressed the Chicago Medical Society, November 12, on "Bleeding Peptic Ulcer."

INDIANA

Medical Reminiscences.—The November meeting of the Madison County Medical Society featured reminiscences of early day practice. Each member was asked to bring a physician who is 70 years old or older as a guest of the society. The society records date back to 1884 and one physician, Dr. George Chittenden, stated in the minutes that he had been a member since 1875. Drs. William M. Garretson, Perkinsville, Lot E. Alexander, Pendleton, and Orlando W. Brownback are the only members now living who were also members in 1890.

IOWA

Society News.—The Northwest Iowa Medical Society was addressed, October 29, by Drs. Bennett A. Melgaard, Sioux City, and Samuel D. Carney on "Clinical Diagnosis in Diseases of Infancy" and "Fractures of the Skull," respectively.——The Linn County Medical Society was addressed, October 9, by Dr. Charles A. Aldrich, Winnetka, Ill., on treatment of acute inflammation of the kidneys in children.

KENTUCKY

Society News.—Dr. Orville R. Miller addressed the Jefferson County Medical Society, November 3, on "Low Back Pain"; Drs. Woodford B. Troutman and William J. Young, Louisville, presented case reports on "Periarteritis Nodosa, with Autopsy" and "Superfluous Hair and the X-Ray," respectively.——The Bourbon County Medical Society was addressed, October 23, in Paris, by Drs. Charles G. Daugherty, Paris, and George H. Gregory, Versailles, on "Abdominal Pains Caused by Diseases Outside the Abdomen" and "Epidemics of Spinal Meningitis," respectively.——The Southwestern Kentucky Medical Association was addressed, October 29, by Drs. Virgil E. Simpson, Louisville, on "Modern Methods of Handling the Diabetic Patient," and Elbert W. Jackson, Paducah, "Diagnostic Value of Cystoscopic Examinations."

Celebration of McDowell Day.—The Southern Medical Association and the Kentucky State Medical Association jointly conducted a program to honor Dr. Ephraim McDowell, the father of ovariotomy, November 5, following the scientific activities of the annual meeting of the Southern Medical Association at Louisville. A sculptor's model of the statue of McDowell placed in Statuary Hall in the Capitol Building, Washington, D. C., was unveiled in the rotunda of the capitol of Kentucky at Frankfort. The visiting physicians formed a motorcade from Louisville to Frankfort and after the unveiling ceremonies proceeded to the McDowell home in Danville, and then to the grave in the public square, where a wreath was laid on the monument erected over his grave by the Kentucky State Medical Association and dedicated in May, 1879. The motorcade then proceeded to Harrodsburg for an inspection of the Pioneer Memorial State Park and then on to Louisville. Dr. McDowell performed the first abdominal operation in the world for the removal of a tumor in 1809.

LOUISIANA

Society News.—The Seventh District Medical Association was addressed, October 9, by Drs. Thomas B. Sellers, New Orleans, on "Constitutional Symptoms of Gynecologic Origin and Treatment of Causative Conditions"; Henry W. E. Walther, New Orleans, "Problems of Cases with Urinary Stones," and Lionel J. Bienvenu, Jr., Opelousas, "Use of Diathermy in Severe Prostatic Conditions."——The Orleans Parish Medical Society was addressed, October 27, by Drs. Charles Walter Mattingly on "Acute Perforation of Peptic Ulcers"; Drs. Edward William Alton Ochsner and Idys M. Gage discussed "Avertin as a Basal Anesthetic."——Dr. Charles J. Bloom addressed the Rapides Parish Medical Society, October 6, at Alexandria on "Feeding Problems of Infancy and Childhood."——The St. Tammany Parish Medical Society was host to the Sixth District Medical Society, October 30, in Covington; the scientific program included papers by Drs. Elbert E. Lafferty, Bogalusa, on "Fracture of the Elbow in Children," and Stanford Chaille Jamison, New Orleans, on pneumonia.

MISSISSIPPI

Society News.—The East Mississippi Four County Medical Society was addressed at Meridian, October 9, by Dr. Terry L. Bennett on syphilis; Dr. Felix J. Underwood, Jackson, spoke on the death rate among the physicians in Mississippi during the past nine months.——The Winona District Medical Society was addressed, October 7, by Drs. George Y. Gillespie, Jr., Greenwood, on "Pyelitis"; Inman W. Cooper, Meridian, "Organized Medicine," and Robert M. Stephenson, Lexington, "Surgical Emergencies."——Drs. Lewis H. Hightower, Itta Bena, and Frank H. Hagaman, Jackson, addressed the Delta Medical Society, October 8, on "Diagnosis in Rural Practice" and "Fractures of the Lower End of the Humerus."——Dr. Van Buren Philpot, Houston, addressed the Northeast Mississippi Thirteen County Medical Society at Corinth, September 16, on "Uterine Hemorrhage."——The fifty-seventh annual session of the Clarksdale and Six Counties Medical Association was addressed in Clarksdale, November 5, among others, by Drs. Phillip C. Schreier and Matthew Wilson Searight, Memphis, Tenn., on "Indications of Low Cervical Cesarean Section" and "Infections of the Cervix Uteri."

NEBRASKA

Society News.—The Omaha-Douglas County Medical Society was addressed, November 12, by Drs. John W. Duncan and Louis B. Bushman on "Postoperative Heat Stroke" and "Headache and Eyestrain," respectively; a symposium on mastoid diseases was conducted by Drs. Donald R. Owen, A. R. Knode, Claude T. Uren and Albert F. Tyler.——At the semiannual meeting of the Nebraska Association of Medical Women, November 8, the speakers and their subjects were Drs. Inez C. Philbrick, Lincoln, "Opportunities of Medical Women"; Esther I. McEachen, "Complete Physical Examination of Children"; Dr. Margaret J. O'Sullivan, Omaha, presented case reports on Vincent's infection of the vagina and cervical occlusion after the menopause.

NEW HAMPSHIRE

Society News.—The New Hampshire Surgical Club was addressed, September 15, at Lake Sunapee, by Drs. Delos J. Bristol, Jr., Boston, on obstetric problems; John F. Gile, Hanover, "Diverticula of the Stomach"; William Jason Mixter, Boston, "Progress in Surgery of the Sympathetic System"; Ezra A. Jones, Manchester, "Low Back Pain"; Dr. Carleton R. Metcalf, Concord, the incoming president, spoke on "History of Surgery in New Hampshire."

NEW JERSEY

Typhoid Carriers.—New Jersey now has thirty-six known typhoid carriers on its list which includes seven added during the last year. The occupation and residence of each typhoid carrier resident in the state is checked at least once a year by local authorities. A regulation requiring a report of all typhoid carriers has been adopted by Ohio, Michigan and Indiana.

Dr. Cushing Honored.—Dr. Harvey Cushing, Boston, will receive, December 6, the award of the Montclair Yale Bowl for 1930 by the Yale Club of Montclair, New Jersey. The presentation follows the custom of the past decade, which recognizes eminent graduates of Yale. The award has not heretofore gone to any professional man or scientist. Dr. Cushing graduated from Yale in 1891.

Additions to Sanatorium Opened.—Opening exercises of the new $1,500,000 additions to the Essex Mountain Sanatorium at Verona were held, October 25. With the new hospital, the bed capacity of the sanatorium will be increased to a minimum of 388 and a maximum of 443 beds. The investment in the sanatorium has now reached $3,913,733. The appropriation for its maintenance for 1930 was $470,000. The hospital is used chiefly for advanced cases of communicable diseases. In the matter of tuberculosis, the county has a joint responsibility with the state, but the state's participation is limited to the acceptance of certain early cases of a curable nature which are treated at the New Jersey Sanatorium for Tuberculous Diseases at Glen Gardner, and to a contribution of approximately $100,000 a year toward the cost of board and care of tuberculous patients. With these two hospitals and the Essex County Hospital for mental diseases at Cedar Grove, the county has an investment of approximately $15,000,000 and the total appropriation for their operation for the present year is $2,175,750. The Verona hospital for mental diseases, known as Overbrook Hospital, had on January 1 a patient population of 2,410. Today there are more than 2,600 patients. The 653 patients admitted last year were an increase of 20 per cent over the year preceding.

Prosecutions by State Board of Medical Examiners.—The following illegal practitioners of medicine were recently prosecuted by the State of New Jersey Board of Medical Examiners:

Schuyler C. Pew, Perth Amboy, held himself out as a masseur and gave electric treatments.

Theodore DeDragic, Atlantic City, held himself out as a Vienna physician and physiotherapist; on failure to pay the fine was committed to jail for thirty days.

Emma L. Garwood, Beverly, advertised as a masseuse and electrotherapist.

Frank Weber, Burlington.

Mary A. Wilson, psychoanalysist of Newark, paid the penalty.

Thomas Parusis, Jersey City; on failure to pay the penalty was committed to jail for thirty days.

Daniel S. Priest, Toms River, druggist, paid the penalty.

Ernest M. Bick, South Orange, prescribed medicine to be taken internally.

Lillian Kallila, Jersey City, paid the penalty.

Aino S. Mateinheimo, Jersey City, paid the penalty.

Eugene Gebauer, Newark, practiced electrotherapy and hydrotherapy; refused to pay the penalty and was committed to jail for five days.

Nicklos N. Barron, Newark, prescribed medicine to be used both externally and internally; paid the penalty.

Abram Taub, druggist, Pompton Plains.

Solomon Boxer, druggist, Ventnot, had a diploma in his drug store showing that he was a graduate of a college of naturopathy but prescribed drugs for his patients.

William Miles, Atlantic City, paid the penalty.

Frieda Korte, Atlantic City; gave electric treatments and colonic irrigations; unable to pay the penalty and, being the third time that she was convicted, was committed for sixty days.

George Lezenby, Jr., Atlantic City, naturopath; paid the penalty.

Charles Schaefer, Sr., Oaklyn, paid the penalty.

Charles Schaefer, Jr., Oaklyn, paid the penalty.

Charles S. Newell, Merchantville, naturopath; paid the penalty.

Elmgott W. Gebhardt, Merchantville, druggist, paid the penalty.

NEW YORK

Health at Albany.—Telegraphic reports to the U. S. Department of Commerce from seventy-eight cities with a total population of thirty-five million, for the week ended November 8, indicate that the highest mortality rate (19.6) was for Albany, and the rate for the group of cities as a whole, 11.7. The mortality rate for Albany for the corresponding week last year was 15.7, and for the group of cities, 11.7. The annual rate for seventy-eight cities for the forty-five weeks of 1930 was 11.9 as compared with the rate of 12.7 for the corresponding period of 1929.

New York City

Faculty Changes at Columbia.—The following recent faculty changes in Columbia University have been announced: Maxwell Karshan, Ph.D., to be associate professor of biologic chemistry; Drs. John P. Caffey, to be assistant clinical professor of diseases of children; Beatrice C. Seegal, to be assistant professor of bacteriology; John D. Lyttle, to be assistant clinical professor of diseases of children; Leon H. Cornwall, to be associate professor of neurology.

Personal.—Dr. John Guttman has been appointed assistant professor of otology at the New York Post-Graduate Medical School and Hospital.——Dr. G. Franchini, director, School of Tropical Medicine, University of Bologna, Italy, recently addressed the Association of Italian Physicians in America on the work of Alphonse Laveran.——Madame N. Dobrovolskaya-Zavadskaya of the Pasteur Institute, Paris, and formerly professor of surgery, University of Voronej, Russia, was recently the guest of the Roerich Institute; she will read a paper at the meeting of the Radiological Society of North America in Los Angeles, December 1-5.

Society News.—The Women's Medical Association of New York City was addressed, November 12, by Drs. Elaine P. Ralli and James Shannon on "A Study of the Five-Hour Blood Sugar Curve in Patients with Varying Degrees of Diabetes"; Priscilla White, Boston, "Care and Treatment of Diabetic Children," and Samuel Standard, "Treatment of the Surgical Diabetic."——Dr. John E. Jennings addressed the New York Surgical Society, November 12, on "Relation of Welch Bacillus to Appendicitis and Its Complications." Dr. J. William Hinton will address the society, November 26, on "Bleeding and Gastroduodenal Ulcers," with report of fifty-two cases.——"Allergic Conditions Encountered in General Practice" was the subject of Dr. Robert Cooke before the Medical Society of the County of Kings, November 14.

Social Hygiene Campaign of Health Demonstration.—An intensive social hygiene campaign was opened, November 1, by the Bellevue-Yorkville Health Demonstration in cooperation with the New York City Health Department, the New York Tuberculosis and Health Association and the American Social Hygiene Association. The object is to inform every resident in the Bellevue-Yorkville district of the risks of the so-called social diseases and to get infected individuals under good medical care. Exhibits were set up for public attendance and talks were given by authoritative lecturers in halls, industrial plants and other meeting places. Publicity was augmented by the distribution of pamphlets, the display of posters and exhibits and motion pictures. In preparation for the November campaign, courses of lectures, provided for physicians, nurses and social workers during October, gave the nurse and patient scientific information on methods of combating venereal diseases.

OHIO

Personal.—Dr. Henry Ware Newman, late of Birmingham, Ala., and formerly of Chinkiang, China, arrived in Cincinnati, November 4, to become associated with Dr. Carey P. McCord in the work carried on by the Industrial Health Conservancy Laboratories. In China he organized a modern mission hospital at the port city of Chinkiang on the Yangtse River, at which place he was medical officer of the port under the Chinese Maritime Customs.——Dr. John W. Clark, Oak Hill, was appointed health officer of Jackson County, October 20.

Society News.—Dr. Temple S. Fay, Philadelphia, conducted the eighth annual graduate course before the Academy of Medicine of Toledo and Lucas County, November 17-21, on "Diseases of the Nervous System."——Dr. Robert H. Ivy, Philadelphia, addressed the annual joint meeting of the Toledo Dental Society and the Toledo Academy of Medicine, November 14, on "Fractures of the Jaw."——Dr. Oskar Klotz, Toronto, Ont., addressed the Academy of Medicine of Cleveland, November 21, on "The Present Status of the Yellow Fever Problem."——The Union District Medical Association was addressed, October 23, by Drs. Edwin W. Mitchell and Willard D. Haines, both of Cincinnati, on "Management, Calculation of Diet and Requirements of Diabetics" and "Diagnosis and Treatment of Nonsurgical Stomach Disorders," respectively.

OREGON

License Restored.—The license to practice medicine of Dr. Horace M. Patton, suspended, April 3, for a six months' probation, was restored, October 2, by the Board of Medical Examiners of the State of Oregon.

PENNSYLVANIA

Society News.—The Lycoming County Medical Society held its annual fall clinic day, November 14, at the Williamsport Hospital; Drs. James G. Logue and Alfred C. Ormond, Jr., spoke on "Cerebral Hemorrhage of New-Born" and "Spinal Anesthesia," respectively; Dr. John P. Harley gave a clinical discussion on diverticulitis of the sigmoid and treatment of bacteremia, and Dr. William E. Delaney, Jr., gave a cinema demonstration of treatment of fractures of the lower extremity.——The Allegheny County Medical Society was addressed, November 18, in Pittsburgh by Drs. John R. McCurdy on "Oxygen Inhalation Therapy: Methods and Technic"; Ernest W. Willetts, "Agranulocytosis," and Lester Hollander, "Eczema from the Allergic Standpoint."——"Acute Intestinal Obstruction from the Standpoint of the General Practitioner" was the subject of Dr. Donald Guthrie, Sayre, before the Elk County Medical Society, October 28.——A symposium on head trauma was conducted before the Washington County Medical Society at Washington, November 12, by Drs. John W. G. Hannon, Clarence J. McCullough and William J. L. McCullough.

Philadelphia

Society News.—Dr. Walter Timme, New York, addressed the Philadelphia Psychiatric Society, November 14, on "Behavior Disturbances as Related to Certain Endocrine Conditions."——The annual Gross lecture was delivered by Dr. William H. Woglom of the Institute of Cancer Research, Columbia University, before the Pathological Society of Philadelphia, November 13, on "Experimental Cancer."

MEDICAL NEWS

SOUTH DAKOTA

Society News.—Drs. Walter A. Fansler and Frederick C. Rodda, Minneapolis, addressed the Watertown District Medical Society, October 15, on cancer and the diseases of children, respectively.——Dr. Clarence E. Robbins opened the program of the joint meeting of the Fourth District Medical Society and members of the Rosebud Society, November 19, in Pierre, with a film on "Surgical Treatment of the Extremities"; Drs. Percy D. Peabody, Webster, and John F. D. Cook, Langford, president and secretary, respectively, of the state medical association were guests at the meeting.

VIRGINIA

Medical Films for Loan.—The extension department of the University of Virginia Medical School has arranged through its bureau of visual instruction for a number of moving picture films and slides to be lent to local medical societies. These deal with medical subjects for physicians and subjects of general interest in educating the public. The films include "Preliminary Hemostasis in Goiter Surgery"; "Puerperal Infection"; "Through Life's Windows," film to educate the public to appreciate good eyesight, and "Light and Lighting" (glass slides only), which explains the theory of light and its action on the human eye. All of these films may be obtained without cost other than transportation charges by applying to George W. Eutsler, acting executive secretary, P. O. Box 707, University, Va.

WASHINGTON

Society News.—The White Salmon Chamber of Commerce held public health night, October 20; the meeting was turned over to the Skamania-Klickitat Medical Society and opportunity was given to the lay public to question physicians on medical matters; the society held its regular semiannual meeting immediately following adjournment of the chamber of commerce health meet; Dr. Christian F. Quevli, Jr., Tacoma, presented a paper on "Fluoroscopy of the Heart and Aorta."——"Placental Hormones" was the subject of a paper by Dr. James B. Collip, Montreal, Canada, before the King County Medical Society, October 7; Dr. James F. Battle, Seattle, presented a case report on tularemia.

WISCONSIN

Steady Increase in Compensation Benefits.—Almost $50,000,000 has been paid to persons injured in industrial accidents under the workmen's compensation law since its enactment in 1911, according to the *Wisconsin Medical Journal*. There has been a steady increase in the amount of compensation paid, beginning with $253,300 in 1912 to $5,402,467 in 1929. During this time 330,554 cases have been reported; the average benefits paid in all cases were $173, of which $130 was paid in indemnity and $42 in medical care. The cost of medical care has almost trebled since the workmen's compensation law was enacted. The average paid per case in 1912 was $21, as compared with an average of $61 during the past year.

Society News.—The La Crosse County Medical Society was addressed recently by Dr. Joseph W. Gale, Madison, on "Treatment of Pulmonary Tuberculosis," illustrated.——Dr. Albert W. Bryan, Madison, addressed the Marinette-Florence County Medical Society, October 9, on "The Current Attitude Regarding Epilepsy, Its Nature and Rational Treatment."——"Colonic Anesthesia" was the subject of Dr. Albert B. Leigh, Kaukauna, before the Outagamie County Medical Society, September 23, and "Adhesions Following Operations on the Gallbladder" that of Dr. Victor F. Marshall, Appleton; Dr. Ernest L. Bolton, Appleton, discussed a case of hemolytic jaundice with an enlarged spleen.——The Milwaukee Roentgen Ray Society was addressed, October 3, by Drs. Eben J. Carey and Harry B. Podlasky, Milwaukee, on "Myogenic Rotary-Lateral Scoliosis" and "The Recent Bloodgood Bone Tumor Clinic," respectively.——"Plastic Surgery in Relation to the General Practice of Medicine and Surgery" was the subject of Dr. George V. I. Brown, Milwaukee, before the Brown-Kewaunee County Medical Society, October 30.

GENERAL

Winners in Health Conservation Contest.—At the recent meeting of the American Public Health Association in Fort Worth, Texas, certificates were awarded to the health departments of Milwaukee, Wis.; Syracuse, N. Y.; East Orange, N. J.; White Plains, N. Y., and Sidney, Ohio, winners in the first Inter-Chamber Health Conservation Contest sponsored by the U. S. Chamber of Commerce.

Deaths from Alcoholism Decreased Last Year.—Deaths from alcoholism in 1929 in the registration area of the United States were fewer than in 1928, or 1927, according to figures compiled by the division of vital statistics of the bureau of the census. The figures for the year 1929 were 4,339; for the year 1928, 4,627, and for the year 1927, 4,372. The death rate from cirrhosis of the liver for the year 1929 was less than for 1928, but more than for the year 1927. The figures for the year 1929 were 8,377; for the year 1928, 8,630, and for the year 1927, 8,098.

Physicians Educated at Home.—The number of medical graduates educated at home colleges compiled for the Middle Western states by the committee on medical education of the Indiana State Medical Association shows that there were 76 per cent educated by the state university in Iowa, 73 per cent in Minnesota, 71 per cent in Indiana, 70 per cent in Nebraska, 58 per cent in Kansas, 45 per cent in Michigan (76 per cent in all schools of the state), 40 per cent in Wisconsin (71 per cent in all schools in the state), 36 per cent in Illinois (85 per cent in all schools in the state) and 25 per cent in Ohio (58 per cent in all schools of the state).

Red Cross Activities.—Among some of the accomplishments noted for the year ended June 30, 1930, were $1,182,350.08 expended for service and disabled ex-service men and their families; $1,341,620.65 for the relief of 95,000 sufferers in 108 disasters; this was $658,267.16 in excess of contributions received for disaster relief; 51,047 Red Cross nurses enrolled for national and international emergencies; 74,437 people trained and certified in first aid; 52,798 people trained and certified in life saving; 37,626 people trained and certified in home hygiene and care of sick; 219,084 pages of braille transcribed for the blind, and 6,930,849 school children enrolled in the Junior Red Cross.

Fellowships in Extramural Psychiatry.—The National Committee for Mental Hygiene has announced fellowships for training in extramural psychiatry open to physicians under 35 years of age, graduates of class A medical schools, and those who have had at least one year's training in a hospital for mental disease, maintaining set standards for clinical work and instruction. A longer period of hospital training is desirable. Applicants able to meet these requirements will not be required to take competitive or oral examinations. Suggestions will be made on the basis of length and type of previous training in the formal psychiatry; all general fitness for the work contemplated, and (in most cases) on the results of a personal interview. The fellowships cover one year's training with assignments at special places, as the Boston Psychopathic Hospital, the Judge Baker Foundation, Boston, the Institute for Juvenile Research, Chicago, and various child guidance clinics in Cleveland, Philadelphia and other cities. The fellowships carry stipends at the rate of $2,000 to $2,500 for the twelve months' period. Applications should be made to Dr. Frankwood E. Williams, National Committee for Mental Hygiene, 370 Seventh Avenue, New York.

Sixty-Five Recoveries from Leprosy.—The U. S. Public Health Service gives a summary of the leprosy cases discharged from the National Leprosarium, which is conducted by the service at Carville, La. More than 300 lepers are under treatment there. During the past ten years, sixty-five lepers have been discharged from this hospital as apparently recovered from leprosy and no longer a menace to public health. The average period of hospital care varied from five to nine years. The shortest period of treatment was one and one-half years and the longest was seventeen years. Fifty-five of these patients received crude chaulmoogra oil by mouth, and sixteen of this group received no other medicine. Twelve received benzocaine-chaulmoogra oil by intramuscular injection and four of these received no other medical treatment. Twenty-one received the ethyl esters of chaulmoogra oil by intramuscular injection, and eight of these received no other medicine. The basic treatment of leprosy is similar to that for tuberculosis, and all lepers at the National Leprosarium, no matter what medicines are given, follow a sanatorium regimen of food, fresh air and rest almost identical with that prevailing in a tuberculosis hospital.

Mortality from Automobile Accidents in 1929.—The U. S. Department of Commerce announces that in the death registration area in continental United States accidents in which automobiles were involved caused 29,531 deaths in 1929 with a death rate of 25.4 per hundred thousand of population. Of this total, collisions of automobiles with railroad trains and with street cars were responsible for 1,958 and 507 deaths, respectively, which, if excluded, would leave 27,066 deaths with a death rate of 23.3. The death registration area in 1929 was composed of forty-six states, the District of Columbia, and nine registration cities in nonregistration states, and included 95.7 per cent of the total population of continental United States. Assuming that the same death rate would hold true for the remainder of the continental United States, the number of deaths in 1929 from accidents in which automobiles were involved is estimated as 30,858 for the whole country, as compared with an estimate of 27,618 for the year 1928. These figures indicate an increase of more than 3,000 deaths from this cause in one year. Comparing the states, the greatest number of deaths occurred in New York (3,192), followed by Pennsylvania (2,331), Ohio (2,320) and California (2,271). Nevada has the highest death rate per hundred thousand of population (51.1). Next in order are California (41.2), Arizona (36.2), Florida (35.5), Ohio (35.3), Indiana (34.1) and Wyoming (33.7). If collisions with railroad trains and street cars are excluded, Delaware, Idaho, Illinois, Montana, Oregon, Rhode Island, Vermont and Wisconsin had fewer deaths than in the previous year. The number of automobile deaths reported for each state and city includes those due to accidents outside the limits of the city or state. Chicago had the greatest number of deaths from collisions of automobiles with railroad trains (26) and with street cars (30).

Society News.—The thirty-fifth annual session of the Seaboard Medical Association of Virginia and North Carolina will be held at Elizabeth City, N. C., December 2-4, with headquarters at Hotel Virginia Dare. The guest speakers will be Drs. Wilburt C. Davison, Durham, N. C., "The Duke Medical School"; Thomas McCrae, Philadelphia, "Functional Disorders of the Colon"; Walter A. Baetjer, Baltimore, "Infectious Arthritis"; Arthur M. Shipley, Baltimore, "Suppurations Within the Chest." Mr. M. F. Cullers, Chicago, will present a motion picture film on "Movements of the Alimentary Tract in Experimental Animals."——At the twenty-seventh annual meeting of the American Association of Railway Surgeons, Dr. Guy G. Dowdall, Chicago, was elected president; Drs. Earl B. Bush, Ames, Iowa, Emile O. Voyer, Minneapolis, and Frank A. Eckdall, Emporia, Kan., vice presidents, and Dr. Louis J. Mitchell, Chicago, secretary, reelected. The next annual meeting will be held in Chicago in November, 1931. This meeting was a joint one with the Surgical Association of the Chicago and North Western Railway and was addressed, among others, by Drs. Waltman Walters, Rochester, Minn., on "Congenital Abnormalities of the Genito-Urinary Tract and Their Treatment"; Sydney Walker, Jr., Chicago, "The Aftermath of 200 Intra-Ocular Steel Cases"; William H. Byford, Blue Island, Ill., "Fractures of the Lower Third of Femur"; John M. Dodson, director, Bureau of Health and Public Instruction, American Medical Association, Chicago, "Physical Examination of the Apparently Healthy," and Arthur E. McMahon, Glenwood City, Wis., "How Shall the General Practitioner Increase His Usefulness?"——Dr. Robert Lee Hoffmann, Kansas City, was elected president of the southwestern branch of the American Urological Association at its meeting in Lincoln, Neb., October 31. Kansas City was selected as the next place of meeting.

Milk-Borne Epidemics in Rural Areas.—The White House Conference on Child Health and Protection has made a report on the serious responsibility for providing clean and safe milk on the part of dairies, distributors of milk and milk control officials. The report shows that rural areas and small towns have the highest incidence of milk-borne epidemics and recommends the observance more fully of preventive measures, especially pasteurization. Communicable diseases transmitted through impure milk make it a hazard to life, the committee points out. A study of milk-borne epidemics during a six-year period, 1924-1929, discloses 258 epidemics involving 10,906 cases and causing 371 deaths. The conference made public the following additional information from the report:

"In 1929 there were 44 milk-borne epidemics, 1,959 cases, and 48 fatalities. Both in 1929 and during the six-year period epidemics in typhoid fever outnumbered other diseases. For 1929 there were 25 typhoid epidemics compared with 177 for the six-year period. A study of the incidence of milk-borne epidemics shows that the milk supply in the smaller cities and country towns is not generally produced and distributed under sanitary conditions and safeguards comparable to those of the large cities. There is a higher incidence of milk-borne epidemics in rural areas, small country towns and small cities with populations from 5,000 to 25,000. The greatest health hazard may be expected in areas of this size in relation to the consumption of unpasteurized milk. Because of the fact that approximately 50 per cent of the population reside in small towns and rural communities, the importance of having pasteurized and wholesome milk is self-evident. Diseases involved in milk-borne epidemics are as follows: diphtheria, dysentery, gastro-enteritis, paratyphoid, poliomyelitis, scarlet fever, septic sore throat, typhoid fever and undulant fever. During the six-year period surveyed with reference to milk-borne epidemics, 34 epidemics of scarlet fever and 22 of septic sore throat occurred. Bovine tuberculosis is being brought under control and thereby the problem of human infection with the bovine strains is being solved. Already large areas have been freed of the disease and at present there are over 27,000,000 cattle under official supervision. In June 986,607 cattle were tested." The committee recommends "that pasteurization be required wherever practicable; that producers, control and educational officials cooperate to give promise of the best and most lasting results, and that the state assume responsibility in milk control where local control is absent."

Government Services

Resignations from the Navy

The following resignations from the navy were recently announced: Lieut. Ernest D. Davis, Jr., effective October 21; Lieut. James T. Parker, effective October 27; Lieut. Charles G. Robertson, effective October 31.

Change of Station in the Navy

Lieut. James J. V. Cammisa to the U. S. S. *Pennsylvania*; Lieut. Comdr. Irving W. Jacobs from the Guardia Nacional, Nicaragua, to the U. S. Naval Hospital, Washington, D. C.; Lieut. Comdr. Julius F. Neuberger from the second brigade, U. S. Marines, Nicaragua, to the naval air station, Lakehurst, N. J.; Lieut. Harvey W. Miller from the Guardia Nacional, Nicaragua, to the U. S. Naval Hospital, Mare Island, Calif.; Lieut. Edward J. Goodbody from the U. S. S. *Arizona* to naval academy.

Changes in Veterans' Bureau Personnel

The October U. S. Veterans' Bureau Medical Bulletin notes the following recent changes in veterans' bureau personnel:

HOSPITALS

Dr. Frank L. Alloway, reappointed at Washington, D. C.
Dr. Roy A. Ashbaugh, appointed at American Lake, Wash.
Dr. Paul J. Borrows, appointed at North Chicago, Ill.
Dr. Richard L. Cook, transferred to Rutland Heights, Mass.
Dr. John E. Damron, appointed at Minneapolis.
Dr. Dudley T. Dawson, resigned at Knoxville, Iowa.
Dr. Durbin C. Day, detailed to Hines, Ill.
Dr. William R. Durham, detailed to Washington, D. C.
Dr. John T. Eagleton, detailed to Hines, Ill.
Dr. Edward H. Fite, appointed at Muskogee, Okla.
Dr. Paul M. Fulmer, appointed at Kansas City, Mo.
Dr. Ernest H. Gaither, appointed at Washington, D. C.
Dr. Michael J. Gold, appointed at Sunmount, N. Y.
Dr. William Goldberg, detailed to Castle Point, N. Y.
Dr. Stanton S. Hoechstetter, detailed to Bedford, Mass.
Dr. John A. Kennedy, detailed to Palo Alto, Calif.
Dr. Joseph V. Kennedy, appointed at Washington, D. C.
Dr. Spencer A. Kirkland, status changed from fee basis to part time at Atlanta, Ga.
Dr. Charles N. O. Leir, resigned at Knoxville, Iowa.
Dr. Horatio D. Luse, transferred to Excelsior Springs, Mo.
Dr. Chauncey C. Maher, appointed at Hines, Ill.
Dr. Francis J. Mantell, detailed to Atlanta, Ga.
Dr. Francis A. Marsh, permanently assigned at Chicago.
Dr. Elson D. McCullough, detailed to Chillicothe, Ohio.
Dr. Charles S. Miller, appointed at North Chicago, Ill.
Dr. Johnnie A. Norris, Jr., appointed at Gulfport, Miss.
Dr. Edward A. Oliver, resigned at Hines, Ill.
Dr. Jesse R. Patton, resigned at Sunmount, N. Y.
Dr. Lester M. Petrie, detailed at Aspinwall, Pa.
Dr. Appleton H. Pierce, appointed at Coatesville, Pa.
Dr. James F. Pitman, appointed at Alexandria, La.
Dr. Cloyd L. Pugh, detailed to Hines, Ill.
Dr. Wilber K. Riley, appointed at Fort Lyon, Colo.
Dr. Eugene W. Rockey, resigned at Portland, Ore.
Dr. Frederick R. Sims, transferred to Somerset Hills, N. J.
Dr. Herbert D. Snyder, transferred to Atlanta, Ga.
Dr. Henry Ladd Stickney, transferred to Sunmount, N. Y.
Dr. William H. Thearle, status changed from fee basis to part time at San Fernando, Calif.
Dr. Raymond D. Tompkins, transferred to Washington, D. C.
Dr. Max J. Wollenman, detailed at Kansas City, Mo.
Dr. Edwin E. Ziegler, permanently assigned at Northport, Long Island, N. Y.

REGIONAL OFFICES

Dr. Joseph P. Delaney, Jr., appointed at Little Rock, Ark.
Dr. Louis J. Genella, resigned at New Orleans.
Dr. George V. Lewis, resigned at Little Rock, Ark.
Dr. Robert E. Parrish, appointed at San Antonio, Texas.
Dr. E. Laurence Scott, appointed at Birmingham, Ala.
Dr. Edgar D. Shanks, resigned at Atlanta, Ga.
Dr. Floyd Webb, reappointed at Nashville, Tenn.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 1, 1930.

Conference on Maternal Mortality

The fifth conference on maternal mortality, held in London, was presided over by the Duchess of Atholl, M.P. Nearly 1,000 delegates representing about 300 organizations attended. Mr. Arthur Greenwood, minister of health, delivered an address in which he said that it was astonishing that, in spite of what had been done, the problem of maternal mortality remained as stubborn as ever it was. Infant mortality and the general death rate had been reduced and yet the number of deaths from the normal process of motherhood was still as great as ever. The greatest expert could not convince him that motherhood should be so dangerous as it is. It was clear that a substantial proportion of maternal deaths were avoidable. He was told that 50 per cent were but he was inclined to place the percentage higher.

A NATIONAL MATERNITY SERVICE

With regard to a national maternity service, he said that behind that ideal lay a good many difficulties. He had an objective to which the government was committed—a national maternity scheme fulfilling all the principles laid down in successive reports. He would like to forge a bond between the national health insurance scheme and the local health authorities which would give an effective maternity scheme on a national basis. The scheme could be framed only when those who were to work it conferred for a general understanding. A resolution was passed expressing agreement with the interim report of the departmental committee on maternal mortality, which supported the previous demand of the conference for an effective national maternity service, based on an increase in the length and content of the training of medical students in obstetrics and on essential services, and urging the coordination of voluntary effort with the work of public authorities. Dr. Brackenbury, chairman of the council of the British Medical Association, said that the resolution had the solid support of the organized medical profession.

The Fight Against Leprosy

The British Empire Leprosy Relief Association is not a charitable institution but a health organization on a grand scale, which endeavors to exercise international action on scientific lines. A meeting of the general committee has been held at the India office. Lord Chelmsford, the president, described a remarkable record of achievement. In Nigeria the association had provided sixty-six settlements and in Nyasaland and Rhodesia fifty-nine for the treatment of leprosy. Its organ, the *Quarterly Leprosy Review*, went to workers and investigators all over the world. Dr. R. G. Cochrane, the secretary, gave an account of his tour through Egypt, the Sudan, Kenya, Zanzibar, Tanganyika, Nyasaland, Rhodesia and South Africa. During the six years of its existence the association had sent out at least a million doses of remedies against leprosy to workers in the field. It had done much for the training of medical officers and for the organization of leper work. But the work was handicapped by lack of funds. It was tragic that in the whole of East and Central Africa there was no one institution comparable to those in India, where medical officers and dressers could get a training in the diagnosis and treatment of leprosy.

Perforation of the Duodenum While Flying

The perforation of a hollow viscus while flying has been recorded, in a letter to the *British Medical Journal*. Surgeon-Commander F. J. D. Twigg reports the case of a corporal in the air force, aged 30, who was seized with abdominal pain in a flying boat at Reykjavik when at an altitude of 2,000 feet. The machine was immediately brought to the water and medical assistance sought from the warship *Rodney*, to which he was transferred. He gave a history of dyspepsia for several years and presented a typical picture of perforation of an abdominal viscus. Immediate operation was performed and a duodenal perforation was sutured. Recovery followed.

Our Deadly Streets: Eighteen Deaths a Day

The general secretary of the National "Safety First" Association, Col. J. A. A. Pickard, in a lecture at the Royal Institution of Public Health said that fatal accidents of all kinds last year destroyed more than half a million years of normal expectation of life. Also the rate of increase in the number of automobiles licensed and in the number of street accidents had been almost identical every year since 1921. On an average, 18 persons were killed every day and nearly 500 injured in street accidents. Every year 1 person was killed for each 400 automobiles licensed and 1 was injured for each 18. In the first three months of the present year in London 66 more people had been killed (an increase of 26 per cent) and 2,260 injured (an increase of 24 per cent) than in the corresponding period of last year. For the first nine months of the present year, street accident returns from 155 provincial districts revealed an increase of 150 persons killed (or 8 per cent) and of 2,989 injured (or 6 per cent) as compared with last year. Among other facts of interest, Colonel Pickard mentioned that half as many females as males are killed in street accidents, that children are much better than their elders in avoiding accidents, that about half the victims of fatal accidents are pedestrians, about one fourth motor cyclists or their passengers, about one eighth other motorists, and the remaining eighth pedal cyclists.

The Position of London Hospitals

The annual statistical review for 1929, just published, shows no falling off in the amount of voluntary contributions, in spite of the industrial depression. On the contrary, they increased during the three years 1927-1929 from $8,000,000 to $8,800,000. If receipts for building and endowment are included, the total voluntary gifts in 1929 were $14,000,000. The total income of the 138 London hospitals dealt with in the review amounted to $18,000,000, a record figure and an increase of $840,000 on the previous year. The work in the voluntary hospitals of London is extending. The increased work is the outcome of gradual change in the part they play. They are no longer only a refuge for the indigent sick; the progress of curative medicine and surgery, while increasing the number of those patients which can effectively be treated, has also led to demands from other classes for services which the voluntary hospitals alone can give. The middle classes are more and more heavily taxed, while the progress of curative medicine and surgery has resulted in more elaborate and therefore more costly methods, which only the well-to-do can command in private. The report therefore claims that the voluntary system is proving adequate to discharge the heavier tasks imposed on it by changing social and medical conditions. It is necessary to point this out at a time when socialists are clamoring for universal state-supported hospitals. One of their main points is that such a necessity as hospitals should not have to depend on charity with its constant appeals by all sorts of devices for more money. As for them the state has a bottomless purse, they overlook the plight of the already overburdened taxpayer as well as the great advantages of high efficiency with low costs of administration of the voluntary system, under which practically the whole of British medicine has been created.

Haffkine, the Bacteriologist, is Dead

The death has occurred, at the age of 70, of Waldemar Mordecai Wolff Haffkine, one of the pioneers of bacteriology, who ranks with Koch, von Behring, Eberth and Kitasato in laying the foundations of modern vaccinotherapy. Born in Odessa of Jewish parentage, he was educated at the local university, from which he graduated in 1884. Until 1888 he pursued research work at the zoological museum of Odessa and then became assistant to the professor of physiology at Geneva. His reputation was so great that after a year in this post he was invited by Pasteur to be his assistant in Paris. At the Pasteur Institute he worked out a scheme of preventive inoculation and in 1893 was invited by the Indian government to devise methods for the arrest of cholera. He worked at the new government research laboratory at Bombay, now called the Haffkine Institute, where he used with good results a modified cholera virus as a protective, a method which he had worked out with Professor Roux in Paris. In 1896 the disastrous epidemic of plague, which broke out in Bombay, led the government to entrust him with the preparation of a vaccine against plague. The Indian Plague Commission reported in 1900 that his vaccine produced a diminution of attack and death rates and the establishment of temporary protection. A series of fatalities in 1902 threw doubt on the methods of manufacture of his vaccine, but they were traced to gross neglect of precautions in administration. The present estimate of the value of his vaccine is that when used in an epidemic of plague it reduces the mortality 85 per cent. What this means can be realized when the many millions of doses used in India are considered. Until 1915 he remained director of the biologic laboratory at Calcutta, when he resigned and went to live in Paris. His last services were given in the Great War. The British forces in France had voluntarily received prophylactic inoculation against typhoid infection, but not against paratyphoid A and B. In view of the entry of troops from India and the transference of divisions from the Mediterranean, it was urged that the complete inoculation should be performed. But Sir William Leishman, director of pathology of the expeditionary forces, opposed immediate action because he feared more severe reactions, which might impede military reinforcement. A committee of eminent pathologists was appointed to consider the question and Haffkine joined them as a kind of assessor. His arguments, supporting those of Sir Frederick Andrews and Sir Andrew Balfour, went a long way to convince Leishman. After a trial on 300 men the T A B vaccine was issued in all areas in January, 1916.

The French Congress of Hygiene

The French Congress of Hygiene, which is organized regularly every year by the Société de médecine publique et de génie sanitaire, was held in the large amphitheater of the Pasteur Institute in Paris, October 20. The opening address was given by Mr. Désiré Ferry, minister of public health. The new minister, a young man with abundant energy, has announced that the revision of the old law of 1902 pertaining to public health, a reform repeatedly promised but never realized, would be submitted to parliament when it opened. Departmental hygienic inspection will be transformed in each department of France in the direction of hygienic services the directors of which will be chosen through competitive examination. Medical inspection of schools will be extended to all the departments of France by means of special personnel consisting of physicians and aids. The municipal sanitary regulations will be replaced by departmental regulations, except for a few local matters, which will remain under the control of the mayors. The transmissible diseases notification of which by the physician has been optional will be placed on the compulsory list. To these, open tuberculosis will be added, heretofore omitted for sentimental reasons. Notification will be followed by isolation of the patients and hospitalization. Supervision of the sources of drinking water will be compulsory; also the construction of suitable dwellings. What the minister did not and could not very well say, since he is a politician, is that the principal reform to be accomplished is the suppression of political influence in the application of the law. The main weak spot of the law of 1902 was that it imposed on the mayor in each commune the duty of applying the law. The mayor, lest he displease his supporters, is tempted to neglect action that might annoy any one. Then, the necessary funds for the creation of hygienic services must be voted by the municipal council and the general council, and these have the power to refuse such aid if they decide to be economical. Public health measures will not be seriously applied in France until their application is placed in the hands of the minister of health and technical councils, and is not left to incompetent or careless mayors and to municipal or departmental assemblies always inclined to be parsimonious in such matters. The address of the minister awakened great hopes in the minds of the many hygienists present and was vigorously applauded. The congress began immediately its scientific sessions. Professor Sacquépée presented a paper on psittacosis, which, toward the close of last year, appeared in a widespread epidemic form extending from Argentina to North America, England, France, Germany, Switzerland, Denmark, the Netherlands and Czechoslovakia. Infection from man to man is rare. The rôle of the Nocard bacillus in psittacosis was carefully studied, and there was a tendency to incriminate rather a filtrable virus. The prophylactic measures are easy to apply, since all that is necessary is to place an embargo on the importation of parrots. As soon as that was done, the epidemic was checked. Dr. Lesage gave the results of studies on infantile statistics. He suggested that the mortality of the first year be figured separately, since it has a special importance. The present statistics of the hospitals that combine the first two years have, therefore, little value. This change has been requested for some time by the Academy of Medicine. Mr. Colin emphasized the importance, in the prophylaxis of a great number of epidemic diseases, of the regular disinfection of the nasal fossae. Basing his opinion on many observations, Mr. Colin demanded the daily application of hygienic care to the rhinopharynx, which would diminish the general mortality by 60 per cent and eliminate, at the same time, many germ carriers. Mr. Béreux supported the view, which is widespread in the United States and in Germany, that the disinfection of rooms by the ordinary procedures is often ineffective, and suggested that they be replaced by painting, which exerts a genuine disinfective action. Mr. Gréhant called attention to the important rôle of congenital syphilis in child mortality. Frequently the serologic reactions are negative in congenital syphilis, and the stigmas appear at a late date. Nevertheless, investigations made in families and hygienic dispensaries bring out plainly the great part played by this cause of stillbirths. Mr. Cassan gave an account of the hygienic measures applied in the department of Aude, last year, following the floods, consisting of the disinfection of the rooms of dwellings, the supervision of drinking water, and the control of vaccinations. Sigallas and Marcotte of Bordeaux presented an apparatus, easy to install in a few hours, by means of which drinking water can be disinfected, in case of an epidemic, with the aid of calcium hypochlorite. The cost of upkeep is insignificant. Mouisset and Tolot presented a resolution of the Comité départemental du Rhône calling attention to the rôle of contaminated objects introduced into the mouth in the transmission of epidemic diseases and demanding the prohibition of whistles and toys that frequently pass from one child to another. Mr. Foucaud spoke on the prophylaxis of pertussis, recommending wider use of the method, in which children cough in front of petri dishes. The cultivation of the Bordet-Gengou bacillus is then easy and enables the examiner to isolate children in the incubation period and to discover the germ carriers. Dr. Masserli of Lausanne demanded the physiologic control of sports in the schools, by the physician. Mr. Bezault presented a study on the purification of muds and garbage. The German procedure which utilizes an old idea of the English and produces biologic fermentation of the muds with liberation of inflammable gases, which are caught in receptacles and used industrially, is preferable to the vacuum drying process and drying in the open air by centrifugalization. The septic fermentation of muds removes all mineral matter from the organic matter, which it converts into gas. This procedure interests only cities with a population of 50,000 or more. Mr. Ginestous described the organization of first-aid stations in the city of Bordeaux, where twenty-five stations have been installed and where special instruction is given to police officers. Mr. J. Reynal presented a popular film on smallpox and its prophylaxis, as prepared for the use of the people of Tunisia.

The Accident Record of Automobile Drivers

The medical examination of automobile drivers, which is intimately associated with the constantly increasing number of automobile accidents, has occupied for some time the attention of the Academy of Medicine. The number of persons who drive an automobile is so great that the idea of requiring all drivers to submit to a special medical examination has been given up, and especially the further plan of requiring periodically a renewal of the examination, which their increasing age would often render necessary. The committee appointed by the Academy of Medicine has recently announced, through its spokesman, Dr. Morax, the conclusions that it reached and that the academy immediately approved. It recommends that a medical examination be required at least of every person who, as a result of a court trial, has received a sentence for his participation in an accident, in order to determine the physical or mental defects of the driver concerned. It demands, in a formal manner, that every automobile driver be provided with a book in which shall be kept a record of the nature of a court sentence, together with infractions of regulations and the results of a medical examination, on the basis of which the driver may be deprived of the right to drive. For drivers of busses and public cars, the city of Paris already requires a medical certificate, also a new examination after each accident. A special service established at the prefecture of police in Paris, of which Dr. Tanon, professor of hygiene at the Faculté de médecine de Paris, is the director, exercises strict control over these matters. An attempt is being made to apply the same ruling to the drivers of all taxicabs, but an understanding with the companies has not been reached.

German Congress on Metabolism Held in Budapest

The German Society of Diseases of Digestion and Metabolism elected for this year's president Baron Alexander Koranyi of Budapest University. As a token of appreciation, the society broke the custom of holding the annual congress alternately in Vienna and in Berlin by selecting Budapest. The prospects for the success of the congress were not encouraging. The economic misery prevailing in Germany was felt at the recent congress of German naturalists and physicians, where the number in attendance lagged much behind that of former congresses. Despite these unfavorable auspices, the Budapest congress exceeded expectation, thanks to excellent management and the interesting scientific material discussed. The congress, which met October 6-8, was opened by Count Klebelsberg, the Hungarian minister of public instruction, with an address entitled "The Cultural Efforts of Hungary," in which the movement was described that resulted in wonderful progress in the medical sciences during the second half of the nineteenth century. During that period administrators and philanthropists regarded it as their noblest task to cherish culture. With them vied government bodies, which erected schools, laboratories and clinics. Klebelsberg expressed confidence that the united strength of the Germans and Hungarians will be able to restrain the destructive forces threatening Europe from the East. The minister and his wife held a reception in the national casino, which furnished an occasion for the guests to form the acquaintance of leading Hungarian scientists.

The scientific work of the congress continued for three days. To avoid discursiveness, the discussions were restricted to one subject each day. On the first day, Vogt of Munich, von Bergmann of Berlin, H. H. Berg of Berlin and Verebely of Budapest discussed changes of form and position of the digestive tract with especial reference to ptosis. Von Bergmann and Verebely stated that the development of technic in fluoroscopy allows deeper inspection into the abdominal organs so that at present it is possible to ascertain, in vivo, changes in form and displacement. Fluoroscopy reveals alteration from the normal anatomic disposition and form of organs, thereby enabling the physician to establish the proper diagnoses and eventually also the indications for surgical intervention. In contrast with this, Bergmann emphasized that the various ptoses and changes of form cannot be regarded as diseases, and that patients are needlessly frightened and worried by changes referring to the sinking and form of intestinal organs, which changes, per se, are not conducive to functional disturbance. Verebely said that, in changes of form and displacement, surgical intervention should be resorted to only when the changes are confined to certain fixed single organs when the patients cannot be helped by any other method of treatment. Several authors demonstrated, by lantern slides, extreme change of place and form that may be observed in abdominal organs without resulting in any pathologic condition. Professor Diedrich of Budapest exhibited a patient in whom a part of the stomach entered an inguinal hernia without disturbing the functioning of the stomach.

Great interest was centered on the theme of the second day. The relation of diseases of the bones to calcium metabolism, internal secretion and vitamines. Fürth of Vienna lectured on the rôle of the epithelial bodies in calcium metabolism, on parathyroid extract-Collip, on the influence of the thyroid gland, the hypophysis, the thymus and the sexual glands on the developments of bones, and on the curative effect of viosterol on rickets. Wieland showed that in Europe 80 per cent of all infants suffer from rickets. While the treatment of rickets used to require months, it now yields after a few weeks of treatment. He cited recent publications which indicate that shortly the poisonous component of viosterol will be separable from the curative one. Then an entirely safe drug will be available. He stated also that the League of Nations is going to establish international units for vitamin D.

Marek and Wellmann of Budapest reported interesting animal experiments. By feeding a whole series of animals with foods deficient in calcium and phosphorus, they succeeded in causing osteitis fibrosa in rabbits, horses, pigeons, pigs, dogs and cats. Experimenting with diverse therapeutic methods to cure the fibrous osteitis, they found that nothing approaches in efficacy the irradiation of the foods, not even the irradiation of the animals themselves.

The problem discussed on the third day was the inflammation of the digestive organs. From the point of view of the internist and bacteriologist, Löwenberg of Berlin said that the bacterial content of the intestine is related to inflammatory disorders of the abdominal organs. The same bacteria are interacting, and the colon and its germ content play an important part in inflammatory conditions of the digestive organs. He lays stress on this, as American authors are prone to relate these inflammatory conditions to purulent inflammations of the tonsils and teeth. The question was elucidated from a surgical point of view by Kaufmann of Berlin, who pointed to those causes which, besides bacteria, may provoke pathologic processes in the digestive organs. For instance, it is admitted by leading clinicians that, in setting up an appendicitis, disturbances of motility, as well as hematogenous infections, may be involved. Similar causes may provoke gastritis and inflammations of the gallbladder. Veil of Jena pointed to the rôle of the nervous system in the production of morbid states in the digestive tract. Westphal of Hanover demonstrated by lantern slides the stimulating and paralyzing action of the vagus nerve on the movements of the appendix. Einhorn of New York demonstrated the bloodless method of dilating the pylorus. Soos of Budapest showed to the foreign guests the dietetic kitchens of the Budapest clinics and explained the individual preparation of dishes, as inaugurated by himself. Professor Dalmady of Budapest took the guests to the curative springs of the Hungarian capital and made known the indications for their use. The Royal Hungarian Opera gave a gala performance in honor of the foreign guests; the city of Budapest entertained them at a banquet in the Hotel Gellert. The members of the congress were invited to the agricultural exhibition, where the different wines of Hungary were presented to them in decorative baskets. The German Societies of Budapest gave a soirée. The women's committee, working under the presidency of Madame Countess Klebelsberg, wife of the minister of public instruction, entertained the ladies who accompanied the members. After the congress ended, some of the members visited the new biologic institute at Tihany, while others were guests of the minister of agriculture in Lillafured, the picturesque health resort, erected recently by the Hungarian government.

BELGIUM

Congress of Gynecology and Obstetrics

During the extraordinary session of the Société belge de gynécologie et d'obstétrique, held at Liége, under the chairmanship of Professor Brouha, three official papers were presented.

The first topic, "The Prognosis of Low Cesarean Section," was presented by Professors Brouha of Liége and Brindeau of Paris. Professor Brouha points out that the results have not been especially good. The record for low cesarean section may be summed up as follows: 4 per cent of mortality and 22.5 per cent of serious morbidity. This intervention, while it presents many advantages, remains a serious operation that should not be resorted to without careful deliberation. From the remote point of view, Professor Brindeau stated that the prognosis of low cesarean section is less grave than the abdominal method. The resulting scar is more elastic and it rarely ruptures during a later pregnancy. Serous adhesions are exceptional; they seldom involve the intestine. Fistulas are rare. Later pregnancies usually develop favorably; the women can undergo the test of labor without great danger. A repeated low cesarean operation is comparatively simple; at the most, adhesions of the old scar, in the wound or in the bladder, may cause trouble.

CANCER OF STUMP OF UTERUS FOLLOWING SUBTOTAL HYSTERECTOMY

The second topic, "Development of Cancer of the Neck of the Uterus Following Subtotal Hysterectomy," was discussed by Dr. Robert Monod of Paris. The author brought out: 1. It appears from statistics collected in cancer centers that the development of cancer in the stump is more frequent than is supposed. 2. Theoretically, while the predisposition of the stump to cancer as a result of subtotal hysterectomy or the presence of a fibroma is not demonstrated, the discovery of a fibroma can no longer be regarded as evidence of a benign type. The belief of the older authors in the amelioration of fibromas coincident with the menopause must be discarded. Immediately following the menopause is when transformations of fibromas into malignant tumors are most frequent and when the development of cancer in the stump of the uterus is most to be feared. 3. Practically, however, the improvements in the technic of subtotal hysterectomy proposed to diminish the danger of cancer in the stump are all defective. The excess of operative deaths ascribable to the increased use of total hysterectomy will be fewer, in skilled hands, than the number of cancers that will be prevented from developing. 4. Radium therapy is best for these cancers. The use of external treatment from a distance (bombardment) appears to be preferable to local treatment.

PUERPERAL ANTIGENIC INFECTION

The third topic, "Puerperal Antigenic Infection," was opened by Dr. Hamm of Strasbourg. The author recalled that the danger today comes more from within than from without. He opposes the exaggerated statement of Metzger: "We are coming to a time when there should be no more deaths from puerperal infection." The bacteriologic research of the twentieth century seems clearly to refute that statement. It conforms more to experimental and clinical realities to confine our ambitions to realization of the time foreseen by Semmelweis "when cases of puerperal infection will become exceptional." This appears to the author the best conclusion of this bacteriologic study, which supports the melancholy reflection of Brindeau: "No woman at confinement is sure of escaping an infectious complication. It must be admitted that here lies the point of gloom in our obstetric art."

Dr. Voron of Lyons groups under the name of autogenous infections those that do not have their origin in external contamination and that are consequently due to a micro-organism located in or on the body of the patient. The clinical aspect of the disorder cannot furnish the scientific proof of the existence of these infections, but it shows us that there are a number of infected persons in whom it is logical to admit that micro-organisms exist either in the genital tracts or at the site of an intragenital focus of infection. It is probable that they constitute an important part of the puerperal fevers that have persisted in the maternity hospitals in spite of the rigorous use of antiseptic measures. On the other hand, their rarity as compared with the total number of confinements in the hospital services, taken with reference to the great frequency of the causes that may produce them, leads to the belief that their appearance is conditioned much more by the variations in the local and general resistance of the parturients than by the virulence of the causative agent. Autogenous infections, whatever may be their frequency, comprise a great majority of cases of moderate gravity but also a few exceptionally grave cases. The prophylaxis of autogenous infections must consider chiefly the terrain. An endeavor must be made to maintain the resistance and to strengthen the defenses of the organism against the offending agent. All the efforts of the clinic and of the laboratory must be directed toward the discovery of the best means of effecting humoral or local immunity of the parturients toward infections post partum.

Effects of Law Limiting Sale of Alcohol

Mr. Vervaek has an article in the *Revue internationale contre l'alcoolisme* that points out the good effects of the law which prohibits the sale of brandy in public places and which followed the decree of Nov. 15, 1918, prohibiting the manufacture and sale of brandy or wine with more than a 15 per cent alcohol content, and of beer with more than an 8 per cent alcohol content. The less drastic law of 1919 maintains the prohibition of the sale at retail of brandy and subjects the dispensing of other beverages to severe regulations The prohibition against the sale of brandy applies to hotels, pleasure resorts, stores, boats, dining cars, work shops and work yards. Trade in alcoholic beverages containing under 18 per cent alcohol is unrestricted. Import duties and consumption taxes have been made four times as high as they were previously. Energetic measures have been employed to prevent the operation of clandestine stills. The law has one grave defect—the regulations applicable to clubs. Clubs are authorized to dispense brandy to their members. The result of this tolerance has been that numerous clubs, frequented by all classes of society and whose *raison d'être* is solely the opportunity of supplying brandy to their members, have been founded.

In general, the law has resulted in reducing the consumption of brandy per capita to one third of the prewar consumption. The consumption of beer has likewise decreased. While the consumption of wine has nearly doubled, the total quantity of wine consumed is still insignificant. The number of places dispensing alcoholic beverages has been reduced one half. There is, however, an increase in the number of places dispensing alcoholic beverages in quantities of from 2 to 6 liters (18,000 in 1927 as against 14,000 in 1914).

Admissions to the hospitals for accidents occurring in a state of drunkenness, or by reason of alcoholism, have been diminished. The psychopathic hospitals note a reduction in the admissions for alcoholic psychoses. The charitable institutions render aid to only one third as many vagabonds and beggars as they did before the war. In the cities and in the rural districts, intoxicated persons are encountered much less frequently. Arrests for drunkenness and for misdemeanors arising therefrom have diminished considerably, in spite of the increase of the population. The proportion of alcohol addicts among persons held in custody is lower than it was ten years ago. The adjoined tabulation gives a survey of the present situation.

	Average from	
	1908 to 1913	1920 to 1925
Persons held in custody previously punished for drunkenness in public.......	6,912	3,742
Persons in custody who were intoxicated when their misdemeanor was committed	4,904	3,084
Persons in custody who were occasional drinkers	553	149
Persons in custody who were habitual drinkers	4,351	2,935

The testimony is unanimous as to the beneficent influence of the law of 1919 on family life, general health, professional work and social life.

BERLIN

(From Our Regular Correspondent)

Oct. 27, 1930.

Congress on Metabolism

The tenth session of the Deutsche Gesellschaft für Verdauungs- und Stoffwechselkrankheiten was held in Budapest, the early part of October, under the chairmanship of Professor von Koranyi.

Professor Strauss of Berlin discussed "The Provision of Proper Diet for Patients," a practical demonstration of which was organized in Budapest by Privatdozent von Soos. In place of the former system, in which every clinic had its central diet kitchen, one central diet kitchen provides the diets for all the university clinics. The food is sent to the distributing centers in the respective clinics. Each distributing center is in charge of a nurse skilled in dietary management. In fact, a considerable portion of the special dishes is prepared in the distributing center. In place of the "menu" system used in other clinics, à-la-carte menus have been introduced. Every morning the menu for the day is brought to the patient, and he selects the dishes that he desires, keeping within the range of the diet that his physician has prescribed. As Professor Strauss pointed out, in emphasis of the distinct advance that characterizes this system, in place of a garrison-like system is one that affords satisfaction to all patients. Great care must be given to the training of the directress of the central diet kitchen and also of the aids in charge of the distributing centers.

Papers on "Bone Diseases in Their Relations to Calcium Metabolism, Internal Secretion and the Vitamins" were presented by the pathologists v. Furth of Vienna and Pick of Berlin; Alwens, internist, of Frankfort-on-Main, and Wieland, pediatrician, of Basel. Whereas formerly nutritional disturbances were chiefly incriminated as responsible for the genesis of rickets, it was learned later that light has a significant rôle. These researches were crowned by the isolation of vitamin D and a knowledge of the value of viosterol, which permits the cure of every case of recent uncomplicated rickets within four to eight weeks; formerly cod liver oil treatment required at least four to eight months. In many cases, however, cod liver oil is not superfluous, since, in addition to vitamin D, it contains also vitamin A. But it must be emphasized that manufactured vitamin preparations must be used with caution; for, in too large quantities, they may produce symptoms of hypervitaminosis and pathologic calcification. They should not be used for every "general weakness," but only when the indications are unequivocal, and only in accordance with a medical prescription.

Dr. Löwenberg of Berlin, Professor Löhr of Kiel and Professor Kauffmann of Berlin presented, on the third day, papers on "Inflammations of the Digestive Organs." The question as to the influence of bacteria on the genesis of appendicitis is still as unsettled as in many disorders of the liver and the bile ducts. Following inflammatory conditions of the throat, there may develop inflammations of the gallbladder, the appendix and other internal organs, and with every recurrence, further irritation symptoms may appear in organs previously impaired by former disorders. The trend of belief is that such recurrences are not due to the action of bacteria or their toxins but to protein decomposition products, which exert a toxic action on previously damaged areas. For the treatment of extremely severe conditions of intestinal inflammation blood transfusions have been employed, of late, with excellent results.

The congress was well attended both by Hungarian and by foreign physicians. On the occasion of the tenth session, Prof. Baron von Koranyi of Budapest, Prof. Knud Faber of Copenhagen, Prof. Hijmans van den Berg of Utrecht, Dr. E. P. Joslin of Boston and Dr. Max Einhorn of New York were elected to honorary membership. The next session will be held in Vienna in September, 1931, under the chairmanship of Professor Falta.

A Film on Tissue Cultures

Dr. A. Fischer of Copenhagen, at present doing research work, on invitation, at the Kaiser-Wilhelm-Institut für Biologie in Dahlem, near Berlin, showed recently a film that dealt with the author's special line of work, the cultivation of tissues. Some of the cultures that he showed dated back eighteen years. Such a prolonged existence can be secured only by frequent washing and frequent renewal of the culture medium. The photographs showed the living cultures with their activities, their growth, their cell division and the active motions in the interior of the cells. Particular interest attached to the sarcoma and the cancer cultures, in which the active and malignant growth could be followed in the minutest detail; also to the observation of wound repair in an injured segment of tissue.

The Society of German Neurologists

The annual session of the Gesellschaft deutscher Nervenärzte was held, this year, in Dresden. The chief topic on the program was "Therapeutisches und Praktisches zum Problem der Restitution im Nervensystem." Boeke of Utrecht treated the subject from the anatomic, Spatz of Munich from the anatomicopathologic, Matthaei of Tübingen from the physiologic, and Foerster of Breslau and Goldstein of Berlin from the clinical point of view. Considerable interest was awakened by the statements of Foerster concerning the restitution of motility and sensitivity. Boeke gave a clear presentation of the present status of research on certain fundamental problems of regeneration in the peripheral and central nervous system. Spatz discussed the morphologic bases of restitution in the central nervous system; Matthaei, the functioning of the central nervous system in experimental interventions on the organism, and Goldstein demonstrated with clinical material that the nature of the restitution is dependent on the influence of four factors: (1) the total capacity of the organism before the onset of the disorder; (2) the greater or less intactness of the whole organism; (3) the amount of energy available for a performance; (4) the environment in which the damaged organism moves. The "totality" must be considered; "catastrophal" reactions must be avoided; in a therapeutic sense, an attempt should never be made to relieve a certain disturbance viewed by itself, but it should always be considered with reference to its significance in relation to the totality of functions that the organism, by reason of its nature, is expected to perform. In the discussion that followed the presentation of the papers, von Weizsäcker of Heidelberg pointed out that we can never examine and analyze scientifically the synthesis of the performances but only the involution. In his closing remarks, during the discussion, Foerster evidently aroused and displeased with the theories and attempted explanations of Goldstein and v. Weizsäcker, expressed himself somewhat as follows: "If, of several members that perform a task jointly (form a working merger), one member drops out, and then, after initial complete abeyance of performance on the part of the complex group, the remaining members of the group take up again the performance of the task, I cannot see why one may not say that the remaining members have taken over the task laid down by the departing member of the group. That is intelligible, and I cannot understand why any one should object to such a mode of expression. Von Weizsäcker and Goldstein say we cannot consider by itself the function of a single portion of the nervous system. If I observe that on stimulation of a peripheral nerve the muscles innervated by it contract, and if, furthermore, I note that after section of this nerve the aforementioned muscles cannot be made to contract through stimulation of the central nervous system, I cannot comprehend why we should not be justified in saying that it is the function of the aforementioned peripheral nerve to innervate the muscles in question. This terminology is certainly centuries old, and if we are to be asked to give it up because some one says it is untenable, may I ask that we be given something in its place that we can understand and that we can then discuss. We can observe not only involution processes (as v. Weizsäcker would limit us) but we can analyze and attempt to explain also synthetic processes. We can from such observations make deductions with reference to the performances of the nervous system. Von Weizsäcker has stated that in our presentations we furnished no scientific proof that the assumption of purposefulness is necessary. I did not claim to have furnished such proof. I declared expressly that, in endeavoring to explain the restitution processes, I constantly reached a point from which further advance seemed impossible, and that personally I could not explain the processes without the assumption of a principle of purposefulness. That was a purely personal confession; I made it plain that it was a concession to my inability to proceed further. It was not my intention to impose this conception on any one."

Of the nonofficial papers, mention may be made of that of F. Kino of Frankfort-on-Main on "Reflex Disturbances Due to Violent Disturbance of the Central Nervous System." In 13 per cent of all cases of pure, recent commotio cerebri there were changes of the reflexes in the lower limbs, doubtless an expression of the mildest type of commotio medullae spinalis; also in mild concussions of the brain attention should be paid to symptoms occurring in the spinal cord. M. Minkowski of Zurich found in eight out of eleven cases of epilepsy pronounced changes in the inferior olivary nucleus. These changes are, however, neither specific nor pathognomonic for epilepsy. K. M. Walthard of Zurich discussed "The Significance of the Psychic Attitude in Relation to the Anatomic Defect." In a film a number of persons were shown who, in spite of irreparable anatomic defects of the extremities, were in the habit of performing normal laborious tasks as housewives or laborers. These persons with healed defects are induced constantly to exercise, develop and transform their capacities, for the most part, through considerations of a clearly thought out type and involving many strong emotions. Their performances, therefore, must not be conceived of merely as substitute performances but as hypercompensations. The seriousness of the anatomic defect is not necessarily decisive for the lasting functional results. With the cooperation of the social welfare centers, the physician should endeavor to induce persons with healed defects to resume their former relations with their environment.

The Weinberg Medal

As an expression of the esteem in which Geheimrat Dr. Arthur von Weinberg, who for many years has served as chairman of the Deutsche Gesellschaft für Gewerbehygiene, is held, that society has founded, in honor of his seventieth birthday, an Arthur von Weinberg medal, which will be bestowed, when occasion warrants, on persons who, in either the scientific or the practical field, have performed meritorious services in the domain of industrial hygiene. At the annual session of the society in Breslau in September, the first series of medals was awarded as follows: Dr. Geib, secretary of the federal ministry of labor (Berlin); Dr. Hamel, president of the federal bureau of health (Berlin); Prof. Dr. Curschmann, Wolfen; Gustav Haupt, Hanover; Geheimrat Prof. Dr. K. B. Lehmann, Würzburg, and Geheimer Oberregierungsrat Dr. Leymann, Berlin.

Geheimrat Eduard Dietrich Honored

On October 10, Wirklicher Geheimer Obermedizinalrat Prof. Dr. Eduard Dietrich, formerly "ministerial director" and head of the medical department of the Prussian ministry of public welfare, celebrated his seventieth birthday. The medical profession honors him because few men have done more for the advancement of the public health of Germany. In the beginning of his career, while serving as district health officer, he organized movements within his jurisdiction, improving the midwife service. In collaboration with Rapmund, he published a highly esteemed work "Aerztliche Rechts- und Gesetzeskunde." Through extension of the field of social hygiene, he gave a new impetus to the central administration of medicine. Not only in scientific fields but along practical lines, he brought about advancement—for instance, in the promotion of public hospitals and public bathing establishments; the care of cripples and the promotion of infant welfare, and, of late years, in aid of the crusade against rheumatism.

Marriages

Brewster Arthur Hopkins, Petersburg, Va., to Miss Margaret Lettie Harris, in Cullen, October 18.

Pompeo S. Milici, New Haven, Conn., to Miss Margaret Thelma Koren of Passaic, N. J., May 8.

Edward B. Vogel, Bellevue, Ohio, to Miss Margaret E. Ruffing of Rochester, N. Y., in October.

LeRoy Warren Saunders, Baltimore, to Miss Dorothy Perkins of Catonsville, Md., November 8.

Donald Bain Moore, Badin, N. C., to Miss Emmie Anderson Brown of Albemarle, October 17.

Arthur W. Records, Franklin, Ind., to Miss Ruth Ann Merritt, in Cincinnati, October 7.

Frank M. Faries to Miss Etta Lee Gray, both of Paris, Ky., in Lexington, August 7.

William Hay Young to Miss Josephine Sheedy, both of Fredonia, Kan., June 3.

Lucius Lester Hutchens to Miss Nedra Johnson, both of Flora, Ill., October 17.

Deaths

David Nichols Dennis ⊕ Erie, Pa.; Jefferson Medical College of Philadelphia, 1881; member of the House of Delegates of the American Medical Association, 1908, 1917, 1918 and 1919; past president of the Erie County Medical Society; member of the American Academy of Ophthalmology and Oto-Laryngology, American Ophthalmological Society and the American College of Surgeons; for many years member of the staff, board of corporators, board of managers and president of the board of managers of the Hamot Hospital; aged 71; died, suddenly, November 15.

Leo John Dretzka ⊕ Detroit; Milwaukee Medical College, 1912; associate professor of surgery, Detroit College of Medicine and Surgery and professor of surgery, Detroit Post-Graduate School of Medicine; served during the World War; member of the American College of Surgeons; on the staffs of the City of Detroit Receiving Hospital, St. Mary's Hospital and the Woman's Hospital where he died, October 12, of a streptococcic infection as the result of an injury, aged 42.

Robert Tarleton Sloan ⊕ Kansas City, Mo.; Medical Department of the University of the City of New York, 1885; past president of the Jackson County Medical Society; formerly professor of internal medicine and head of the department, University of Kansas School of Medicine; aged 69; on the staffs of St. Luke's Hospital, St. Joseph's Hospital and the Research Hospital, where he died, October 22, of carcinoma of the gallbladder with metastasis to the liver.

Arnold Steven Taussig ⊕ Denver; Gross Medical College, Denver, 1891; Medical Department of Washington University, St. Louis, 1893; past president of the Denver County Medical Society; member of the American College of Physicians; served during the World War; on the consulting staff and since 1922 chairman of the medical advisory board, Sanatorium for the Jewish Consumptives' Relief Society, Spivak; aged 60; died, October 11.

Edward Franklin Leonard ⊕ Chicago; Harvey Medical College, Chicago, 1902; College of Physicians and Surgeons, Chicago, 1903; member of the American College of Physicians; formerly assistant professor of neurology, University of Illinois College of Medicine; on the staff of the Grant Hospital; aged 58; died, October 31, of heart disease.

Wisconsin Illinois Royster, Raleigh, N. C.; Bellevue Hospital Medical College, 1869; member of the Medical Society of the State of North Carolina; formerly professor of medicine, University of North Carolina School of Medicine, and professor of the practice of medicine, Leonard Medical School; aged 85; died, October 24.

Horace Frank Stiltner ⊕ Windrock, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1909; past president of the Anderson County Medical Society; served during the World War; aged 55; died, October 22, in St. Mary's Hospital, Knoxville, of injuries received in an automobile accident.

William B. Bowman ⊕ Los Angeles; St. Louis University School of Medicine, 1910; member of the American College of Physicians, American Roentgen Ray Society, Radiological Society of North America and the American College of Radiology; aged 45; died, October 20, of coronary thrombosis.

Benjamin S. Herring, Wilson, N. C.; University of Michigan Medical School, Ann Arbor, 1900; member of the Medical Society of the State of North Carolina, and the American College of Surgeons; medical director of the Moore-Herring Hospital; aged 53; died, October 6, of tuberculosis.

Addison L. Stump, Derby, Ohio; Starling Medical College, Columbus, 1896; member of the Ohio State Medical Association; county health commissioner; formerly member of the state legislature and county board of education; aged 68; died suddenly, October 19, of heart disease.

David Newton Jones ⊕ Long Beach, Calif.; Rush Medical College, Chicago, 1890; formerly mayor of Gaylord, Minn., and superintendent of the hospital; member of the Minnesota State Board of Medical Examiners, 1896-1898; aged 74; died, October 24, of uremia.

Charles Henry Ludlum ⊕ Hempstead, N. Y.; Medical Department of the University of the City of New York, 1865; for many years member and president of the board of education; aged 87; died, October 12, of mitral stenosis, arteriosclerosis and chronic nephritis.

Edwin Price Vaughan, Hillsboro, Texas; University of Louisville (Ky.) School of Medicine, 1908; member of the State Medical Association of Texas; for six years city health officer and for four years county health officer; aged 52; died, August 12.

William Tassie Wilson, Dundas, Ont., Canada; Victoria University Medical Department, Coburg, 1892; member of the American Psychiatric Association; formerly medical superintendent of the Ontario Hospital, Cobourg; aged 62; died, August 2.

Charles E. Zerfing ⊕ Los Angeles; University of Pennsylvania School of Medicine, Philadelphia, 1895; member of the American College of Surgeons; aged 57; died, August 31, in the Queen of Angels Hospital, of chronic diffuse nephritis.

Harvey T. Billick, Monongahela, Pa.; College of Physicians and Surgeons, Baltimore, 1885; formerly mayor, member of the city council and the school board; aged 79; died, September 22, of chronic myocarditis and acute gastritis.

Enoch T. Jones, Hampton, Ark.; Memphis (Tenn.) Hospital Medical College, 1901; member of the Arkansas Medical Society; past president of the Calhoun County Medical Society; aged 62; died suddenly, October 1, of heart disease.

Jesse Munroe Anderson, Columbus, Ga.; University of Georgia Medical Department, Augusta, 1899; member of the Medical Association of Georgia; aged 55; died, October 12, in Asheville, N. C., of pulmonary tuberculosis.

John W. Ragsdale, Smithville, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1913; American Medical University, Kansas City, 1920; aged 44; died, August 13, in the Sumter County Hospital, Americus.

George Lester Hoege, Sarasota, Fla.; University of Wooster Medical Department, Cleveland, 1870; for many years member of the board of health and school board of Fostoria, Ohio; aged 83; died suddenly, October 6.

Garnet Woolsey Holmes, Chatham, Ont., Canada; University of Toronto Faculty of Medicine, 1898; aged 56; died, recently, at the Public General Hospital, of heart disease, following an operation for appendicitis.

George Chapin Jenkins, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1896; formerly on the staff of the Abington (Pa.) Memorial Hospital; aged 56; died, October 24, of heart disease.

George Wesley Green ⊕ Ely, Nev.; University Medical College of Kansas City, Mo., 1904; past president of the White Pine County Medical Society; aged 53; died, October 20, of heart disease and carcinoma.

Benjamin George Stephenson, Toronto, Ont., Canada; University of Illinois College of Medicine, Chicago, 1912; University of Toronto Faculty of Medicine, Toronto, Ont., 1918; aged 48; died, August 28.

John Charles McDonald, Little York, P. E. I., Canada; McGill University Faculty of Medicine, Montreal, Que., 1905; served during the World War; aged 55; died, July 15, of carcinoma of the stomach.

Jesse Pickrell Simpson ⊕ Palmer, Ill.; Missouri Medical College, St. Louis, 1899; served during the World War; member of the school board; aged 61; died, October 21, of carcinoma of the liver.

David Livingstone Heggie, Brampton, Ont., Canada; University of Toronto Faculty of Medicine, 1890; L.R.C.P., Edinburgh, L.F.P.S., Glasgow, Scotland, 1891; aged 62; died, August 17.

W. H. Olmstead, Taylor, Pa.; Columbus Medical College, 1890; member of the Medical Society of the State of Pennsylvania; aged 68; died, September 12, of arteriosclerosis and nephritis.

Margaret Gardner Forrest Hogg, Vancouver, B. C., Canada; University of Glasgow Medical Faculty, Glasgow, Scotland, 1907; died, June 25, as the result of an automobile accident.

Herman Sheldon Farr, Madrid, Iowa; State University of Iowa College of Medicine, Iowa City, 1881; aged 77; died, October 20, of cerebral hemorrhage.

Joseph Pierre Gadbois, Montreal, Que., Canada; Laval University Faculty of Medicine, Quebec, Que., 1892; aged 62; died, August 22, of pneumonia.

Arthur Gunn, Weston, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1895; aged 57; died, August 15.

John Brewer Gilchrist, Norton, N. B., Canada; Bellevue Hospital Medical College, New York, 1891; aged 65; died, August 17.

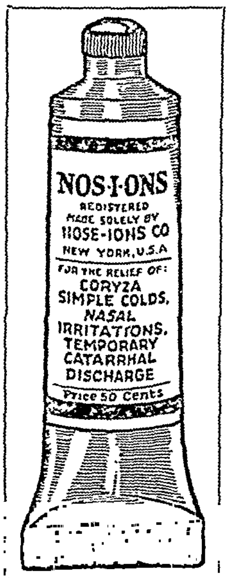
Bureau of Investigation

MORE MISBRANDED NOSTRUMS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

Knewitz's Stopake Powders.—G. Knewitz of East St. Louis, Ill., shipped in January, *1929,* into Missouri a quantity of Knewitz's Stopake Powders that were declared adulterated and misbranded. The preparation was found to consist of capsules, each containing essentially 3 grains of acetanilide and 6 grains of aspirin. It was declared adulterated because the product was labeled as containing 3½ grains of acetanilide per dose. It was declared misbranded for the same reason and, further, because the curative claims, that it was a remedy for neuralgia, toothache, rheumatism, backache, earache, women's pains, etc., were false and fraudulent. In June, *1929,* judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16868; issued July, 1930.*]

Mentho-Mustard. — The Mentho-Mustard Company of Athens, Ga., shipped to Florida in December, 1928, a quantity of Mentho-Mustard that was declared misbranded. Analysis showed the product to be an ointment with a base of the consistency of petrolatum, containing small amounts of volatile oils including mustard oil, camphor, menthol, and wintergreen. The therapeutic claims that the preparation was a remedy for influenza, rheumatism, bronchitis, croup, asthma, pneumonia, and various other conditions were declared false and fraudulent and in October, *1929,* judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed. —[*Notice of Judgment 16853; issued July, 1930.*]

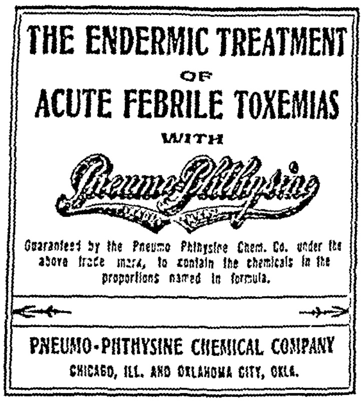


Nos-I-Ons.—The Nos-I-Ons Company of Brooklyn, N. Y., shipped in March, *1929,* to New Jersey a quantity of Nos-I-Ons that was declared *misbranded.* Government analysts reported that the product consisted essentially of petrolatum, quinine sulphate, salicylic acid, camphor and eucalyptol. The claims on the trade package, to the effect that it was a remedy for catarrh, grippe, bronchitis, hay fever, measles, scarlet fever, etc., *and was good for scalp and skin diseases,* were declared false and fraudulent. In September, *1929,* judgment of condemnation and forfeiture was entered and the court ordered that the product be released to the Nos-I-Ons Company on payment of costs and the execution of a bond conditioned in part on the truthful relabeling of the preparation. — [*Notice of Judgment 16776; issued May, 1930.*]

Foley's Cold and Grippe Tablets.—Foley and Company of Chicago shipped in January, *1929,* to Wisconsin a quantity of Foley's Cold and Grippe Tablets that were declared misbranded. The preparation was found to consist essentially of acetanilide and cinchonine compound, red pepper and an extract of a laxative plant drug. The claim that it was a remedy for influenza and neuralgia was declared *false and fraudulent* and in June, *1929,* judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16863; issued July, 1930.*]

McLean's Tar Wine Cough Balm.—The Dr. J. H. McLean Medicine Company of St. Louis, Mo., shipped into Kansas in November, 1928, a quantity of Dr. J. H. McLean's Tar Wine Cough Balm that was declared misbranded. The product was found to consist *essentially of small amounts of extracts of plant drugs, including licorice, wood tar,* sugar, alcohol and water. The claims that the preparation was a remedy for influenza, coughs, spasmodic croup, etc., were declared false and fraudulent, and in June, 1929, judgment of condemnation *and forfeiture was entered* and the court ordered that the product be destroyed.—[*Notice of Judgment 16874; issued July, 1930.*]

Pneumo-Phthysine. — The Pneumo-Phthysine Chemical Manufacturing Company *of Chicago shipped in February, 1929,* into Missouri a quantity of Pneumo-Phthysine that was declared misbranded. The preparation was essentially a clay poultice, containing glycerine, creosote, small amounts of guaiacol, oil of wintergreen, formaldehyde, and a quinine compound. The claims that the preparation was a remedy for acute fevers, mastitis pharyngitis, tonsillitis, coughs, typhoid fever, etc., were declared false and fraudulent. In July, 1929, the Pneumo-Phthysine Chemical Manufacturing Company appeared as claimant, judgment of condemnation was entered, and the court ordered that the product be released to the claimant to be truthfully relabeled upon the execution of a good and sufficient bond.—[*Notice of Judgment 16864; issued July, 1930.*]



THE ENDERMIC TREATMENT
OF
ACUTE FEBRILE TOXEMIAS
WITH
Pneumo-Phthysine
Guaranteed by the Pneumo Phthysine Chem. Co. under the above trade mark, to contain the chemicals in the proportions named in formula.
PNEUMO-PHTHYSINE CHEMICAL COMPANY
CHICAGO, ILL. AND OKLAHOMA CITY, OKLA.

[In April, 1929, "Pneumo-Phthysine" became "Numotizine."]

Williams' 101 Tonic.—The Interstate Drug Company of Quitman, Ga., shipped in January, 1929, into Florida a quantity of Dr. Williams' 101 *Tonic that was declared misbranded.* The preparation was found by the federal chemists to consist essentially of epsom salt, quinine sulphate (about 5 grains to the fluid ounce), ferric chloride and glycerine. The claims *that the product was a remedy for malaria, influenza,* bilious fevers, etc., were declared false and fraudulent and in October, *1929,* judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16859; issued July, 1930.*]

Solomon Whitfield Smith's Venereal Medicine.—S. W. Smith and Company of Valdosta, Ga., shipped in August, 1928, into Florida a quantity of Solomon Whitfield Smith's Venereal Medicine that was declared *misbranded.* The federal chemists reported that the preparation consisted essentially of turpentine oil, copaiba, copper sulphate (blue vitriol), alcohol and water. The claim that the preparation was a remedy for gonorrhea and syphilis *was declared false and fraudulent, and in* September, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16865; issued July, 1930.*]

Healing Ointment. — The Manhattan Drug Company, Brooklyn, N. Y., shipped into Massachusetts a quantity of Healing Ointment that was declared misbranded. It was found to be an ointment having a petrolatum and wool-fat base, with zinc oxide, boric acid, carbolic acid, sulphur, menthol, and other volatile oils. The claims that it was a remedy for eczema, itch, piles, all skin diseases, etc., were declared false and fraudulent and in September, *1929,* judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16792; issued May, 1930.*]

Rapid Quinine Laxative Cold Tablets.—The G. P. Steyh Importing Company of St. Louis, Mo., *shipped in February,* 1929, into Illinois a quantity of Rapid Quinine Laxative Cold Tablets that were declared misbranded. The tablets were found to contain acetanilide, chalk, baking soda, milk sugar, extracts *of plant drugs,* including a laxative drug, and a small amount of alkaloids, but no quinine. The product was declared misbranded, first, because the label would deceive and mislead purchasers into the belief that the product contained quinine, which it did not; further, the therapeutic claims that the product was a remedy for influenza, fever, neuralgia, malaria, etc., were declared false and fraudulent. In May, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16875; issued July, 1930.*]

Vapomentha Salve.—The Rox Chemical Company, Louisville, Ky., shipped in April, 1927, to New York a quantity of Vapomentha Salve that was declared misbranded. Analysis showed it to consist essentially of petrolatum, with turpentine oil, and volatile oils including camphor, menthol and eucalyptus. The claims that it was a remedy for croup, pneumonia, coughs, influenza, asthma, etc., were declared false and fraudulent, and in October, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16795; issued May, 1930.*]

Case's Antiseptic Ointment.—The Case Manufacturing Company of Trenton, N. J., shipped in May, 1929, to Pennsylvania a quantity of Case's Antiseptic Ointment that was declared misbranded. The ointment was found to consist essentially of a tallow base, containing small amounts of carbolic acid and volatile oils, including camphor and sassafras oil. The claims that the product was a remedy for abscesses, sores of long standing, piles, eczema, erysipelas, bunions, pneumonia, caked breast, etc., were declared false and fraudulent, while the claim that the ointment was "made from a combination of oils extracted from herbs, roots and barks" was declared false and misleading. In September, 1929, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment 16871; issued July, 1930.*]

Correspondence

"STAPHYLOCOCCUS TOXIN IN THE TREATMENT OF FURUNCULOSIS"

To the Editor:—Interest in the skin-necrotizing toxin produced by *Staphylococcus aureus*, particularly as to its clinical value in the treatment of recurrent furunculosis when administered hypodermically, led to a summary of an article recently published (Weise, E. C.: Staphylococcus Toxin in the Treatment of Furunculosis, The Journal, August 2, p. 324) in which the following statements were made:

1. The skin-necrotizing toxin produced by *Staphylococcus aureus* was employed in the treatment of chronic furunculosis.
2. Of twenty-four cases treated, nineteen showed an arrest of the furuncles.
3. Two cases of furunculosis in diabetic patients were uninfluenced by the injections.
4. Favorable response to this treatment was noted in other types of staphyloderma.

It is to be noted that a skin-necrotizing toxin produced by *Staphylococcus aureus* was employed. This particular exotoxin produced necrosis when injected intradermally into rabbit skin and could be neutralized by the serum of rabbits immunized to it, neutralization of toxin by antitoxin occurring in multiple proportions.

Recently a communication (The Journal, September 13, p. 815) suggested that a certain amount of correction be made in the statement by Dr. Weise that "in 1928, Greenbaum and Harkins reported inconclusive results from the use of staphylococcus filtrates; but as their filtrate had little toxicity for rabbit skin it could not have contained any considerable amount of the toxin described here." In the same letter it is stated that "Our results were far from inconclusive and our filtrate was of excellent quality." The degree of quality was not questioned. The absence of any considerable amount of the skin-necrotizing toxin was taken, however, as the point of differentiation and these writers clearly state, "Experimentally our filtrate showed little toxicity for rabbit skin" (Greenbaum, S. S., and Harkins, M. H.: Staphylococcus Filtrates in Chronic Staphylococcic Pyodermas, The Journal, May 26, 1928, p. 1699). They also found it unnecessary to use dilutions. On the other hand, the preparation I used was highly toxic for rabbit skin, causing definite necrosis. It was also found necessary to use this preparation in definite dilutions.

Greenbaum and Harkins devoted most of their paper to the reports of intradermal tests on three different classes of patients. They also reported results of treatment of five cases of various pyodermas, only two of which were cases of furunculosis. They further state: "From a therapeutic point of view no definite statement can as yet be made. Only five patients were treated, two for furunculosis, both of whom were relieved for three and five months, respectively," and, further, "The exact dosage for treatment purposes is unknown." Though I realize that the small series of twenty-four cases of furunculosis reported by myself is inadequate to base any far-reaching conclusions on, it is of sufficient value, together with the working dose suggested and the follow-up data, to make at least a tentative therapeutic statement.

Ellwood C. Weise, M.D., Bridgeport, Conn.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

POSSIBILITY OF UNDULANT FEVER TRANSMISSION THROUGH MILK

To the Editor:—Some time ago I read an editorial in which you cautioned the public as to the danger of Bang's bacillus disease or undulant fever, and I ask for your opinion that I may be properly advised in the case described: The undersigned is a member of our city council and months ago the council passed an ordinance requiring persons desiring to sell raw milk either to have their cows tested for Bang's bacillus disease or to mark on the milk bottle caps, "Not tested for Bang's disease." Through the action of one or two raw milk dealers who have admitted that they have disease in their herds, they have filed a statement endeavoring to restrain the council from enforcing that part of the ordinance relating to Bang's disease. The statement by the dealers denies Bang's disease; denies the transmissibility to human beings through the medium of milk; denies any harm or danger from the disease; denies the efficacy of pasteurizing milk so far as it destroys germ activity; denies any and all reliability of test for Bang's disease, and complains of the hardship to the milk dealers in the loss of cattle by testing, and the loss in business by marking the milk bottle caps, "Not tested." Please omit name.

M.D., Pennsylvania.

Answer.—The occurrence of undulant fever in human beings as the result of the ingestion of raw milk containing the organism of contagious abortion has been conclusively demonstrated. While some individuals appear to be naturally immune to the disease and others acquire a relatively mild infection, the majority of patients with undulant fever experience a severe illness. Most investigators have found that the average duration of illness is from three to four months. It has been repeatedly demonstrated that complete, carefully supervised pasteurization will destroy organisms of the *Brucella* group. The agglutination test on the blood or milk-whey is the most reliable procedure available at the present time for the detection of the infection in live stock. In a report of "Recent Progress in Studies of Undulant Fever," by H. E. Hasseltine, Surgeon, United States Public Health Service, which appeared in *Public Health Reports*, July 18, it was stated that "It is probable that less than 1 per cent of infected cows will escape detection by the agglutination test, and these will very likely be found on retests of the herd." The national associations representing the medical milk commissions and the producers of certified milk have already prescribed action for the elimination of infected cattle from herds supplying certified milk. Many milk producers are now pasteurizing certified milk. There is no evidence that the testing of cattle and the segregation of infected animals has worked any great hardship on dairymen. It has been a common observation of veterinarians that cows with *Brucella* infection do not produce as great a quantity of milk as noninfected animals. Hardenbergh, director of

QUERIES AND MINOR NOTES

laboratories of the Walker-Gordon Laboratory Company, Inc., has stated (*J. Am. Vet. M. A.*, March, 1930, pp. 298-306) that cows which are free from *Brucella abortus* infection have consistently produced an average of one quart of milk a day more than cows in the infected group. There is no evidence that the sale of milk and dairy products has decreased in the many communities in which pasteurization has been practiced for many years.

EFFECTS OF SOAP SUDS ENEMAS

To the Editor:—What is the present status, its effect on the rectum and colon, of the use of soap suds or a weak solution of green soap employed as enemas, either high or low?

M.D., Kentucky.

Answer.—An occasional enema of soap suds has its definite indications in some instances, for example, the relief of fecal impaction, the removal of barium sulphate after a fluoroscopic examination or when there is an urgent need for rapid evacuation of the colon. There is no excuse for the repeated use of enemas, day after day, or even less frequently as a means of obtaining evacuations. Such procedures lead to an overdistention of the colon, the development of atony of the musculature of the bowel and in the condition of so-called irritable bowel, often a symptom of some other abdominal lesion, to an increase of the irritability. This manifests itself clinically by digestive disturbances, a feeling of abdominal distention, cramps, increased constipation or alternating constipation and diarrhea. It is far better to relieve constipation by a high residue diet, exercise and the occasional use of a retention oil enema.

EFFECTS OF PROLONGED USE OF ALKALINE POWDERS

To the Editor:—Given a demonstrated case of duodenal ulcer controlled by diet and alkaline powder the formula of which is: precipitated calcium carbonate, 1½ ounces (45 Gm.); sodium bicarbonate, 2 drachms (8 Gm.), and heavy magnesium oxide, 2 drachms (8 Gm.), will the daily use over a period of years of this powder in drachm doses, i. e., 1 drachm (4 Gm.) each twenty-four hours, be more likely to predispose the patient to stone formation or arteriosclerosis than otherwise as time goes on? In other words, is the prolonged use of this powder harmless? Kindly omit my name.

M.D., Utah.

Answer.—The prolonged use of any alkaline powder may be harmful and may lead to kidney changes. Alkalis should not be given indiscriminately without frequent examination of the urine to denote the presence of an alkaline urine and also the presence of albuminuria. If kidney changes do become manifest, arterial changes would necessarily follow.

Regarding the question of urinary calculi, oxalate stones are not uncommon with long continued use of alkalis.

DIAGNOSIS OF CONGENITAL SYPHILIS

To the Editor:—I have a man, aged 44, under my care, who has been troubled with fainting spells off and on for about twenty years. Examination of the blood gave a positive Wassermann reaction. A series of treatments of neoarsphenamine and mercury about one year ago resulted in a negative Wassermann reaction but no marked amelioration of symptoms. I then lost track of him, but he returned to me and I have given him twenty weekly injections of tryparsamide. A blood test taken one week after treatment was discontinued showed a negative Wassermann reaction and a 3+ positive Kahn reaction. From my examination I think that the man's condition is congenital. Any help you can give me will be appreciated. Please omit name.

M.D., Ohio.

Answer.—It is doubtful whether the patient has congenital syphilis. If his fainting spells are the only apparent sign of his disease and they have been of twenty years' duration one should investigate them for the possibility of their being epileptic attacks. The description suggests nothing that might be indicative of central nervous system syphilis, although a spinal puncture might be done to make sure. Neoarsphenamine and mercury would be better drugs to use than tryparsamide for this patient.

POLIOMYELITIS

To the Editor:—I have been taught that the prognosis of a case of poliomyelitis can be determined in the early stages by a cell count of the spinal fluid. Will you please advise me as to the truth of this?

S. Cutter, M.D., Brooklyn.

Answer.—It is probable that the prognosis of poliomyelitis cannot be determined by a study of the cell count of the spinal fluid. In the early stages the pleocytosis is made up of lymphocytes. Later the cell type changes to leukocytes. One can simply state the number of cells, giving an idea of the extent of the meningeal reaction, which is probably related to the amount of parenchymatous damage. But one should be hesitant about making a grave prognosis on the basis of such a criterion.

ANATOMY OF THE EYE

To the Editor:—Would you kindly inform me on the following points of anatomic difficulty (eye): 1. Is the uveal coat of the eye at all adherent to the sclerotic along the line of the ora serrata in man? 2. Is the ciliary muscle at all adherent to the sclerotic in the same region? 3. Is there positive agreement among anatomists that the fibers of the zonule decussate? As regards question 1, it seemed to me that in sheep the posterior ciliary border was to a certain extent glued down to the sclerotic and required more force to separate it here than elsewhere. As regards question 2, Terrien (Le Cristallin, figs. 11, 12, 14, 15 and 91) says that the ciliary muscle is partly attached to the lamina fusca of the sclerotic. Waldeyer, quoted by Gray (Anatomy, p. 1018), and Sattler (Salzmann's Anatomy, p. 224, references 187 and 188) agree, but the location of this attachment requires definition. As regards question 3, Salzmann (Anatomy of the Eyeball, pp. 112 and 224) does not mention decussation. Arthur Thomson (Anatomy of Human Eye, 1912, p. 29 and illustrations) seems skeptical. Retzius (Helmholtz: Physiological Optics **1:** 406, fig. 139; Rauber: Lehrbuch der Anatomie, ed. 2, 1920, Kopsch, fig. 166), Gerlach (quoted by Berger: Encyclopédie française d'ophthalmologie **1:** 361) and Landolt (diagram in Clarke's Refraction, fig. 32, p. 36), however, appear to uphold this view. Gullstrand (Helmholtz: Physiological Optics **1:** 405) assumes decussation. Arthur Thomson's stereoscopic photos do not show it and Cattaneo (Quelques observations sur le mechanisme de l'accommodation, *Ann. d'ocul.* **166:** 48 [Jan.] 1929) could not observe any decussation of the zonular fibers clinically in his cases of aniridia. Piersol's Histology (fig. 408, p. 356) does not show decussation. The fibers of the zonule certainly do not seem to decussate near the lens as Retzius depicts them.

R. A. Yeld, M.D., Edgewood, B. C.

Answer.—1. This question can best be answered by direct quotation from the Kurzes Handbuch der Ophthalmologie **1:** 61, in the section by Eisler on Anatomy of the Human Eye: "The choroid is perforated posteriorly by the optic nerve and here hugs the nerve and the sclera closely by participating in the formation of the lamina cribrosa that transfixes the nerve. Anteriorly it is grown together with the scleral spur and the fibers of the inner wall of the sinus venosus sclerae. Otherwise, the blood vessels and nerves that enter the choroid by perforating the sclera form a firm bond between the choroid and the sclera; in the region of the fovea centralis retinae there is also a rather firm adhesion to be found. Otherwise, the adherence between these two coats is rather loose. A loose external layer of the choroid known as the lamina suprachoroidea and consisting of rather heavily pigmented leaves adheres so firmly to the sclera that no microscopic differentiation is possible and when torn away leaves brown flocculent pigment on the sclera. This was formerly known as the lamina fusca sclerae."

2. No.

3. The consensus among the authors quoted by Eisler in the Handbuch seems to be that there is a decussation of the fibers of the zonule of Zinn. This is further borne out by the embryologic work of Ida Mann. In her book on "Development of the Human Eye," figure 155 clearly shows a definite decussation, although she does not discuss that question specifically.

SIGNIFICANCE IN INFANT OF SLIGHT RISE IN TEMPERATURE

To the Editor—A girl, aged 8 months, of normal delivery, on breast and supplementary feeding of modified cow's milk and a maltose-dextrin preparation, weight 19 pounds (8.6 Kg.), with negative clinical and laboratory observations confirmed by a pediatrician, has had a temperature between 99 and 100 in the twenty-four hours for the past thirty days. The thermometers have been checked up. What causes may be considered for the febrile condition? Please omit name and address.

M.D., Indiana.

Answer.—In these modern days, in which there are one or more thermometers in every household, the baby's temperature is frequently taken once or more daily. It is obviously tru that inflammatory conditions may exist in the body and caus temperature fluctuations in infants and children. Otitis, py litis, inflamed lymph nodes, sepsis, tuberculosis and many oth inflammatory lesions may cause febrile reactions.

On the other hand, there is a large group of children who have persistent slight elevations of temperature which seem to depend more on physiologic and constitutional characteristics than on inflammatory conditions. Not all children have a mean rectal temperature of from 98.6 to 99 F. A certain number of apparently normal infants have a slightly higher temperature. Not a few children who are lively show a slight elevation after exercise, which falls to normal after resting. An elevation of temperature of 1 or 2 degrees which is continuous, of the so-called monothermia type, is of less significance than one in which there are marked daily fluctuations.

Many of the infants and older children who show hyperthermia or some peculiarity of constitution are of the sensitive, neuropathic or vasoneurotic types. They are frequently anemic and asthenic, are easily fatigued, have headaches and perspire profusely.

The point of the whole matter seems to be that a constancy in rectal temperature is expected which does not uniformly exist in all infants and children. It must be assumed that the heat regulating mechanism varies in different individuals. In some it has an unvarying stability, in others a considerable degree of lability. This individual difference undoubtedly frequently explains why so many infants and children have a more or less constant temperature of 99 or 100 during apparently perfect health and why the same children will have 101 or 102 F. for some trivial reason. Sometimes the degrees of fever is influenced by the depth of insertion of the rectal thermometer. The higher the thermometer is inserted, the greater the degree of temperature. It is frequently advisable to compare the axillary with the rectal temperature. Not infrequently the latter will be one or two degrees higher than the former.

The crux of the matter seems to be that a certain group of children show an elevation of rectal temperature somewhat higher than normal over an extended period of time. If every possible pathologic condition is excluded and the baby is otherwise in apparently good health, the use of the thermometer should be discontinued and the slight elevation of temperature disregarded.

DIET FOR A GUINEA-PIG

To the Editor:—Will you kindly inform me regarding the normal diet for a guinea-pig, also whether or not white rats are preferable to guinea-pigs for experimental work on nutrition and pulmonary changes?

M.D., Philadelphia.

ANSWER.—Guinea-pigs do well on a normal diet of carrots or other common vegetables, hay and oats as much as they like. If fresh vegetables are available, water is not necessary. Generally speaking, white rats probably are preferable to guinea-pigs for experimental work on nutrition. As to which animal would be preferable for experimental work on changes in the lungs, nothing definite can be said without some knowledge of the nature of the changes it is proposed to study.

NEGATIVE WASSERMANN AND SYPHILIS

To the Editor.—A man, aged 27, has blotches on his face and, under his nose, a sore that is raised, hard and indurated. It has the appearance of a chancre. As the result of a Wassermann test taken at one laboratory, which reported Wassermann 4 plus and Kahn 4 plus, he was given neoarsphenamine, intravenously 0.45 Gm., and four days later, 0.6 Gm. His face cleared up. He went to a hospital, where some one told him that he did not have syphilis. Wassermann tests taken there and at another laboratory were both negative. Could the prompt intravenous medication eliminate all trace of syphilis with only two injections?

M.D., Chicago.

ANSWER.—The agreement of the Wassermann and Kahn reactions supporting the clinical features of the case make the diagnosis of this case a well established one. It is entirely possible that the neoarsphenamine given, though a small amount, could have cleared up the general infection sufficiently to cause a negative Wassermann reaction for at least a time. The information given at the hospital was not correct. No one can state that a person who has had antisyphilitic treatment and is at the time of examination free from all signs of syphilis is free from the disease. An opinion on this point should be formed only after long study of the case.

ACROPARESTHESIA IN PERNICIOUS ANEMIA

To the Editor:—A woman, aged 65, is suffering with "acroparesthesia" of the hands and feet, particularly of the hands. She has pernicious anemia, from her blood picture, which was as follows: March 6, 1930, hemoglobin, 38 per cent (Dare); red blood cells, 1,520,000, with anisocytosis and poikilocytosis; color index, 1: 2. Under the influence of liver her blood picture grew progressively better. At the same time she has the other symptoms, such as glossitis; before the use of liver she had severe attacks of diarrhea, this having subsided at present. I have not tested for free hydrochloric acid, fearing that this would be too great a strain on her myocardium, which is poor. I would like to have her get some relief from the severe pain, numbness and tingling of her hands and feet. There is no question that she has changes in the cord, and my belief is that these changes were evident before any changes in the blood picture. The reason I say this is that the acroparesthesia is of more than two years' duration and the blood picture was normal one year ago. Please omit name.

M.D., New York.

ANSWER.—Many cases of pernicious anemia develop the paresthesias before the blood picture shows evidence of anemia. Usually, however, there is a tendency to macrocytosis even before anemia develops. These cases respond with most difficulty to any form of specific therapy. Longcope recently reported encouraging results with large doses of liver or liver extract, using as much as 1½ pounds of liver a day. Raw pork stomach ground up and mixed with orange or tomato juice or other fruit juice, or desiccated, defatted hog stomach have also been of much value. At least from a half to 1 pound of raw stomach or from 20 to 40 Gm. of the desiccated product should be given daily.

IRRITATION OF PENIS FROM CONTRACEPTIVE SUPPOSITORY

To the Editor:—I recently saw a young man who, shortly following intercourse, experienced marked swelling and pain of the external genitalia, particularly the penis. He states that immediately prior to one act a commonly used brand of vaginal suppository was inserted into the vagina. He was similarly affected several years ago under the same circumstances. Examination revealed a markedly edematous penis and scrotum with concomitant bilateral palpebral edema. The latter, he states, appeared at the same time as the genital swelling. How do you account for the palpebral involvement? What was the offending agent in the suppository? Are such cases on record? Please omit name.

M.D., New York.

ANSWER.—Contraceptive vaginal suppositories and globules may contain acid mercury preparations, sulphonated bitumen, oxyquinolin sulphate (chinosol), quinine, boric acid or hypochlorites. For these drugs, individuals may show a marked idiosyncrasy. In susceptible individuals, local irritation and inflammation of the penial skin occurs, while extensive absorption may produce renal disturbances with subsequent development of edema in parts of the body where the subcutaneous tissue is of rather loose consistency.

PROPHYLAXIS OF OPHTHALMIA NEONATORUM

To the Editor:—We have had considerable trouble at the San Pedro General Hospital in the way of irritation in new-born infants' eyes from silver nitrate used as a prophylaxis against ophthalmia neonatorum. In order to eliminate this difficulty, which is objectionable principally because of its disconcerting effects on parents, we are endeavoring to use some other equally efficient antiseptic. For this reason we would appreciate your opinion on the following matters: 1. Is mild silver protein (argyrol) as effectual as silver nitrate? 2. If so, what percentage would you suggest for the strength of solution? How long can such a solution be kept without losing its antiseptic qualities, or becoming irritating? Would you suggest anything else?

A. W. WARNOCK, M.D., San Pedro, Calif.

ANSWER.—1. No. No colloidal silver or silver protein is as efficient as silver nitrate in the prevention of gonorrheal ophthalmia.

2. One per cent mercurochrome-220 soluble has been used successfully as a preventive, but no statistics have been compiled on this nor is this view shared by all ophthalmologists.

3. Better continue to use a fresh 1 per cent silver nitrate solution and be safe.

LIQUID PETROLATUM FOR OIL IMMERSION LENS

To the Editor.—It might interest microscopists to know that liquid petrolatum is not only "just as good" but is actually superior to cedar oil for oil immersion work for the following reasons: 1. The field of vision is just as clear. 2. Liquid petrolatum is more stable. 3. It is easily removed from the slide at any time by wiping. 4. With liquid petrolatum it is easier to clean slides for reuse. 5. The lens never becomes gummed and clouded. 6. The fingers do not become gummed and sticky on handling. 7. It is cheaper and more convenient.

JOHN B. WELLS, M.D., Scott, Ark.

ANSWER.—Liquid petrolatum is being used in many preparations instead of cedar oil for oil immersion lenses. It is satisfactory in many ways, as Dr. Wells has stated. It must be remembered, however, that there are different grades of liquid petrolatum with different refractive indexes, and to obtain the best results, liquid petrolatum must be especially selected for the purpose.

BABINSKI REFLEX

To the Editor:—What interpretation should one place on the Babinski reflex when, after the inner side of the plantar surface of the foot has been irritated, the toes remain in the neutral position? No sign of the flexion or extension appeared.

ABRAM LIPKIS, M.D., Los Angeles.

ANSWER.—In plantar stimulation the normal response, of course, is a downward movement of the big toe. Frequently, however, in quite normal individuals there is no movement whatever. This lack of movement is suggestive of some pathologic disturbance when the other big toe moves downward well on plantar stimulation. It is frequently said that, when one big toe moves down and the other one does not move at all, this is an unequivocal Babinski reflex. This is frequently of significance in early lesions of the pyramidal tract.

DIAGNOSIS AND TREATMENT OF ASTHMA

To the Editor:—I have a younger brother, aged 13, who has vasomotor rhinitis and has had three asthmatic attacks. Protein sensitization tests have shown sensitization only to dust. Do you think injections of dust extract will help this condition? Do you think removal to a different climate will help? If so, what localities are suitable for such conditions? Will residence in a suitable climate cure the condition permanently or will the condition return with removal back to New York after a time?

M. D., New York.

Answer.—Dust extracts help some patients sensitive to dust. It is impossible to say whether a change of climate will help. The majority of patients are not permanently relieved by change of climate and the condition usually returns when they return home. A careful study of the case by some one specializing in the diagnosis and treatment of allergic diseases might be helpful.

Book Notices

A SURVEY OF THE LAW CONCERNING DEAD HUMAN BODIES. By George H. Weinmann, LL.B., Attorney and Counselor at Law. Bulletin of the National Research Council, Number 73. December, 1929. Issued under the Auspices of the Committee on Medicolegal Problems. Paper. Price, $2. Pp. 199. Washington, D. C.: National Research Council of the National Academy of Sciences, 1929.

This is a compilation and digest of laws relating to the dead human body. The law does not specifically define what a dead human body is. It uses the term synonymously with corpse, and by inference rather than by direct statement looks on the latter as the body of a human being whose vital functions have ceased. A number of court decisions have established that the more or less completely disintegrated remains of a human being are no longer a dead human body in the legal sense.

The legal status of parts removed from the living body is of interest especially to surgeons and to hospitals. Under the common law such parts belong to the person from whom they have been removed, who or whose legal representative alone has the right to specify the disposition to be made of such parts. New York, North Dakota, Oklahoma and South Dakota recognize this right by specific statutory enactment. In the last three states the statute, if strictly interpreted, might require burial and removal permits for parts surgically removed. Although a stillbirth statistically has not been a living human being and is not a death, the laws requiring the reporting of stillbirths as such make the laws relating to the dead human body applicable to stillbirths. Because of the wide variation that exists in the different states in the definition of stillbirth, Weinmann recommends the adoption by all states of the definition proposed by the International Health Board of the League of Nations. Property right does not exist in the dead human body and it cannot therefore be bartered, bargained for or sold. However, the living person, who, under the common law, may specify by will or otherwise the method of disposal of his body and the performance of a necropsy on it, may during his life contract to sell his dead body and may collect payment on the contract before his death, provided the terms of the contract do not outrage public decency or menace the public health. The right that exists in a dead body is the right of custody, the right to possession of the body in the condition that it was in at the time death supervened. In general, the right of custody follows the laws of inheritance of property. The right of custody carries with it the duty of sepulture. A number of odd provisions of the common law that place the responsibility for burial, and hence give the right of granting permission for necropsy, on the tenant or owner of a building, the master or owner of a vessel, or the superintendent of a hospital in which death has occurred and the body remains unclaimed have been set aside in most jurisdictions by the so-called anatomic acts, which specify the disposal to be made of unclaimed dead bodies.

Since the person entitled to the custody of a dead human body is entitled to it in the condition it was in at the moment of death, the making of a postmortem examination requires the consent of the person entitled to custody. If the circumstances of death are such as to require action by the coroner or medical examiner, such official does not need the consent of the next of kin. Most states have statutes that prescribe the rights and duties of the coroner or medical examiner in the matter of inquests and necropsies. In the case of consent necropsies, the consent need not be in any specified form nor in writing unless written permission is specifically required by statute; Connecticut is the only state having such a statutory provision. The performance of an unauthorized necropsy renders him who performs it liable to a civil suit for damages. Since the dead body is not property, property damages may not be awarded in such cases. If the jurisdiction in which the suit is brought recognizes the doctrine of mental pain and anguish, the sum to be awarded lies in the discretion of the court. If this doctrine is not recognized, usually only nominal damages may be awarded. It has been held in many court decisions that the removal of parts or organs from the body, even when consent for necropsy has been given, is illegal unless necessary to establish the cause of death. Although the matter has never come up for court decision, Weinmann states it as his opinion that under certain circumstances the presence of spectators at a permission necropsy might be construed as causing mental pain and anguish to surviving relatives and might therefore render the pathologist who permits spectators to be present liable in damages. Facts learned at necropsy are admissible as evidence and do not come under the rule of privileged communications.

The laws regulating embalming deal chiefly with the licensing of embalmers, with the composition of the embalming fluid to be used, and with the contagious disease in which embalming is necessary. The transportation of the dead body may involve compliance with the death certificate and burial permit regulations of the state from which the body is shipped and of the state into which it is shipped, with federal quarantine, customs and immigration regulations, and with interstate and intrastate commerce regulations. The usual method of disposal of the dead human body is by interment. Although under the common law burial need not be in a recognized cemetery, this matter is governed by the burial permit regulations. Some states require a special permit for cremation. Some others require the authorization of the coroner or medical examiner. Exhumation of a dead body may be ordered by the coroner or medical examiner if circumstances have come to light since burial that make examination of the body necessary. In civil actions, courts are loath to order exhumation unless some important private or public issue is involved. The regulations relating to exhumation have as their chief aim the safeguarding of the public health.

DIE CHIRURGIE: EINE ZUSAMMENFASSENDE DARSTELLUNG DER ALLGEMEINEN UND DER SPEZIELLEN CHIRURGIE. Herausgegeben von Prof. Dr. M. Kirschner und Prof. Dr. O. Nordmann. Lieferung 28. Band III. Chirurgie der Nerven. Von Prof. Dr. W. Lehmann. Paper. Price, 11 marks. Pp. 833-980, with 73 illustrations. Berlin: Urban & Schwarzenberg, 1930.

DIE CHIRURGIE: EINE ZUSAMMENFASSENDE DARSTELLUNG DER ALLGEMEINEN UND DER SPEZIELLEN CHIRURGIE. Herausgegeben von Prof. Dr. M. Kirschner und Prof. Dr. O. Nordmann. Lieferung 29, Band II. Teil 2. Die Operationen an den Knochen und Gelenken. Von Priv.-Doz. Dr. A. Winkelbauer. Paper. Price, 16 marks. Pp. 1829-2028, with 98 illustrations. Berlin: Urban & Schwarzenberg, 1930.

The twenty-eighth and twenty-ninth sections, the last of the system of Die Chirurgie, have arrived. The former, by Lehmann of Frankfort, takes up the subject of surgery of the nerves, and the second, by Winkelbaüer of Vienna, covers operations on the bones and joints. In their general appearances handling of the subject and make-up, these two sections resembl their predecessors. The section on surgery of the nerves covers the subject in a systematic manner, discussing anatomy and pathology and ending with a good bibliography. The first part of the section is devoted to general underlying principles; the second covers operations on specific nerves, starting with the cranial nerves, going downward through the spinal nerves, and ending with operations on the peroneus and the tibialis. Perhaps it is because the subject matter lends itself so easily to a systematic exposition or perhaps it is because of the way Professor Lehmann handles the subject that this section avoids one of the faults seen in so many of the previous sections; namely, that the material is not accessible. The section on surgery of the bones and joints is similarly divided into a general part dealing with the operative treatment of bones and joints as a whole and a special part dealing with the individual bones and joints. The book is confined to technic and covers only what has not been covered in the sections on bone and joint surgery that have already appeared.

These two sections complete a six volume system of surgery by Kirschner and Nordmann. The system is written in German and has appeared in twenty-nine different sections, which have come from the press from time to time over the period of more than a year. According to the advertisements, a durable encasement is furnished to enclose the various sections which make up any one volume. The various sections vary from 200 to 400 pages, are paper bound, and are rather poorly held together. The illustrations are good. Some of the color plates are excellent. Each volume is indexed for itself and a general index is to come with the system. The type is good but the reader who is accustomed to the average American work, in which subjects are separated from one another by the use of different kinds of type and by deep paragraphing, will be disappointed when trying to pick material out of the solemn-looking page. The whole field of surgery has been covered. The material has been

BOOK NOTICES

gathered together by men whose knowledge of the subject is beyond question. The individual authors have written their particular assignments in a careful, thorough and exhaustive manner.

However, the worth of this system must be weighed by other similar works that are available. As compared to the best recent systems of surgery written in English, Die Chirurgie will be a disappointment. Although the subject matter is excellent, one cannot say that the material is treated any better than in many other systems.

Military Preventive Medicine. By George C. Dunham, M.A., M.D., Dr.P.H., Major Medical Corps, U. S. Army. The Army Medical Bulletin, Number 23. Cloth. Limited distribution and not for sale. Pp. 1051, with 197 illustrations. Carlisle Barracks: Medical Field Service School, 1930.

Army Medical Bulletin 23, a book of more than a thousand pages, elucidates such problems in military preventive medicine as sewage treatment and disposal, the protection of the water and food supplies and the prevention of diseases transmitted by insects. This bulletin shows what can be done in camp to keep flies and mosquitoes from breeding, how pasteurization plants can be quickly set in operation, how water supplies can be made potable by chlorination, and the disposal of refuse from the kitchen and stables. The numerous illustrations include fly traps, incinerators, latrines and septic tanks. This basic information on healthful camp life has, in this volume, been placed under one cover for the first time. The author has not endeavored to cover the entire field of military preventive medicine. His object was to provide medical officers with information that will help them determine by study and inspections the effect of sanitary conditions on health, as well as to supervise the application of measures that have been enforced to protect the health of troops. Special attention, therefore, has been given to the control of communicable disease among troops, and to environmental conditions that affect the spread of disease. There are score cards on several pages which students can fill in, thus practicing the inspection of dairy farms, milk plants, and other parts of a camp. This book will be useful to all medical military personnel.

Medicinal Drugs of India. By Kaviraj Balwant Singh Mohan, Vaidya Wachaspati (Pb.) A.M.A.C. (Mad.), Research Scholar, Lahore. Cloth. Price, Rs. 2/-, Foreign, $3. Pp. 281. Lahore: Atma Ram & Sons, 1930.

This book should be useful to the practitioner of "European" medicine in India to enable him to identify the native drugs and to understand the uses made of them. From it are learned such facts as that Hingu is the Sanskrit name for asafetida, "Badam-I-Shirin" for sweet almond, and Dalchini for cinnamon. Occasionally one runs across acquaintances such as Chaulmugra, Dhatura and Kamala; but, in general, the student of materia medica finds himself lost in a to him unknown jungle of strange herbs. The author admits that it generally was a custom with the Sanskrit writers to make exaggerated statements about the uses of various compound preparations, but that "if the sound principles and methods . . . with the time honored recipes of reliable efficiency were not there, the Ayurvedic system of medicine would have been dead by this time in the struggle for existence." Nearly 80 per cent of the people living in the villages of India are on the verge of starvation. When these poor people fall ill they find scientific treatment so expensive that they cannot afford to pay even for their prescriptions. Naturally they are obliged to try some drugs at the hands of a village quack who is unscientific as well as uncertain about the diagnosis and treatment of any ailment. "Surely, if our allopathic friends devote their attention . . . toward some systematic study about the indigenous medicine . . . they can do excellent service to the suffering humanity with much less cost." What sorely troubles the author is that, though India is rich in many important medicinal drugs, most of them are imported into the country because of lack of government initiative and encouragement; and that, in some instances, drugs are exported from India to foreign countries only to be returned as finished products at much higher prices. Research work in the Ayurveda would "yield an unlimited field for bringing out much useful material which will not only be an asset to the country's economic uplift but will materially benefit the whole world."

Sadism and Masochism: The Psychology of Hatred and Cruelty. In two volumes. By Wilhelm Stekel, M.D. Authorized English version by Louise Brink, Ph.D. Cloth. Price, $10 per set. Pp. 441 and pp. 473. New York: Horace Liveright, 1929.

These are among the most recent volumes in a series now being issued in English by Horace Liveright. Stekel is generally recognized as a disciple of Freud who has gone far beyond Freud himself, as well as other followers of the great psychologist, in his methods and in the extent of his practice. He is recognized as perhaps more romantic than scientific. In these two volumes he is largely concerned with the relationships of hatred and cruelty to psychologic reactions. It has been known since these subjects were popularized by Havelock Ellis that there is a clear relationship between the sex element and both the infliction and the enjoyment of cruelty. Dr. Stekel makes this clear by the recital of numerous cases from his practice and from psychosexual literature. His manner of presentation is such as to make almost anything he writes most interesting.

Über die akute und chronische gelbe Leberatrophie mit besonderer Berucksichtigung ihres epidemischen Auftretens in Schweden im Jahre 1927. Von Prof. Dr. Hilding Bergstrand. Paper. Price, 14 marks. Pp. 114, with illustrations. Leipzig: Georg Thieme, 1930.

The format, print and illustrations of this book are attractive. The author regards acute yellow atrophy of the liver as a distinct disease caused by a specific agent, most likely infectious in nature. Syphilis, pregnancy and other conditions believed to cause acute yellow atrophy are held to be predisposing factors. Some 150 cases were studied and of these 97 occurred in Sweden in 1927, their incidence describing a curve like that of an epidemic disease. In the city of Gothenburg catarrhal icterus and acute atrophy described parallel curves. At the most only one of the 97 patients had syphilis and of the 72 women in the series none were pregnant or recently delivered. The book records the results of a careful study of acute yellow atrophy on the basis of the material indicated. The nature of the material, the relation of acute atrophy to catarrhal icterus, the cause, symptoms and forms of acute atrophy, its pathologic anatomy and its etiology are discussed. At the end are many case reports. The changes in the liver, the acute as well as the chronic, are described thoroughly and well illustrated. The monograph is an important addition to the literature of acute yellow atrophy of the liver. The suggestion, which is supported by the circumstances, that it concerns a specific, infectious disease merits serious further consideration.

Laboratory Manual in College Physiology. By Cleveland Pendleton Hickman, Ph.D., Professor of Zoölogy in De Pauw University. Cloth. Price, $1.10. Pp. 116. New York: The Macmillan Company, 1930.

This little manual is well suited to meet the needs of the courses in elementary physiology taught in colleges and normal schools, or wherever the facilities are limited. The directions for the laboratory work are brief and explicit, and each group of experiments is preceded by an introductory discussion of the functions of the system to be studied. The experiments are well chosen, both for the instructiveness and for the ease with which they may be performed.

Viaggi ed escursioni scientifiche di Lazzaro Spallanzani. Di Giacomo Pighini. Prefazione di Guglielmo Bilancioni. Paper. Price, 40 lire. Pp. 441, with illustrations. Bologna: Licinio Cappelli, 1929.

Many famous Italians have been remarkably versatile. It will be recalled that Leonardo was a painter, anatomist and engineer; Galileo, a mathematician, astronomer and musician; Michelangelo, a sculptor, painter and architect. Among these must be mentioned Spallanzani, who was an all-round naturalist. He was not a famous specialist in anatomy, yet he made minute anatomic studies that led to important physiologic discoveries; he contributed to a knowledge of plant physiology; though not an expert chemist, he had enough practical knowledge to enable him to shed new light on the subjects of digestion, respiration, mineralogy and volcanology. He was a physicist, chemist, geologist, botanist, anatomist, physiologist. He was a great traveler, collecting many and valuable specimens for his museums. On his voyages he made copious notes, many of which are in his published volumes. T[illegible]ok is made up of such notes selected and carefully edited, with explanatory comments by Pighini. They are of greater interest to the general scientist, the geologist, the zoologist, the botanist and the volcanologist than to the physician. They are largely concerned with his observations on rocks, mountains, lakes, volcanoes and marine life. Spallanzani's voyages took him to many mountains and lakes of Italy, including Sicily, to Switzerland, to Turkey and to various parts of the Adriatic and Mediterranean seas. The notes attract one both by their style and by the information they contain. They reveal the remarkably keen powers of observation and deduction of this famous eighteenth century investigator.

Diseases Transmitted from Animals to Man. By Thomas G. Hull, Chief Bacteriologist, Illinois Department of Public Health. With an introduction by Veranus A. Moore, Director, New York State Veterinary College, Cornell University. Cloth. Price, $5.50. Pp. 350, with 29 illustrations. Springfield: Charles C. Thomas, 1930.

This book is a systematic presentation of present-day knowledge of its subject. In the first section the diseases of animals and of birds are considered, beginning with their history and covering bacteriology, methods of dissemination and control. The second section reviews rodent diseases, the third human diseases spread by animals, the fourth animals as passive carriers of disease organisms in botulism, tetanus and gas gangrene, and the fifth a review of the rôle played by each animal in the spread of disease. There are also good author and subject indexes. The book is written in pleasing succinct style. It is well annotated. Each part has a brief summary. The knowledge it contains should be available to every physician, veterinarian and public health worker.

Die Prokto-Sigmoskopie und ihre Bedeutung für die Diagnostik und Therapie der Krankheiten des Rektum und des Sigmoideum. Von Geheimrat Professor Dr. Hermann Strauss. Second edition. Paper. Price, 17.50 marks. Pp. 99, with 78 illustrations. Leipzig: Georg Thieme, 1930.

This volume is a decided improvement over the first atlas issued by the author in 1910. It is profusely illustrated with natural color plates illustrating all of the more common diseases that can be diagnosed by the use of the anoscope, the proctoscope and the sigmoidoscope. Methods of examination and pathologic reports are described in the text in contrast to normal observations. It is unfortunate that such a beautiful work is not thought worthy of a better binding.

The Story of a Surgeon. By Sir John Bland-Sutton, Bt., F.R.C.S., Vice-President and Consulting Surgeon to Middlesex Hospital. With a preamble by Rudyard Kipling. Cloth. Price, $3.50. Pp. 204, with 26 illustrations. Boston: Houghton Mifflin Company, 1930.

At a time when numerous readers among both the public and the medical profession are writing and talking ecstatically about the romance and interest of the autobiography from "The Story of San Michele," it is refreshing to read a work with the charm and interest and, above all, with the essential honesty of this autobiography of Sir John Bland-Sutton. Influenced, no doubt, by the work of his father as a naturalist, his medical life is replete with references to all living things. His acquainanceship with actors, authors, ministers and statesmen was extensive. His humor is inspiring, his candor striking. His life reveals not only his own nature but the development of the most important period of medical science, including asepsis and bacteriology. His influence on anatomy and gynecology was an important one. His book is written with a sedate yet journalistic style, and he reflects in it all the things that have interested him. An unusual feature is the last chapter, in which he carefully records his own contributions to literature and his impression of their merits. Every surgeon and gynecologist will find in this book much that is of value. Anatomists will find it particularly in their field, and the general reader will learn much that will amaze and interest him.

Handbuch der Geisteskrankheiten. Herausgegeben von Oswald Bumke. Band IV. Teil 4: Allgemeiner Teil. Bearbeitet von K. Birnbaum, P. Nitsche und W. Vorkastner. Paper. Price, 44 marks. Pp. 421. Berlin: Julius Springer, 1929.

This volume of the system of psychiatry edited by Bumke is concerned with general therapy and prophylaxis of mental diseases, forensic psychiatry and the borders of psychiatry with general cultural and social sciences. The book fulfils the promise of the editor in making this handbuch a great work.

Medicolegal

Vesicovaginal Fistula Following Hysterectomy

(Brear v. Sweet (Wash.), 284 P. 803)

A physician, Sweet, removed the uterus of the appellant, Brear, because of what appeared to be a cancerous growth in it. Immediately after the operation, a retention catheter was employed. After this was removed on the third day, the patient voided urine naturally until the evening of the eighth day. Then urine was found to be leaking from the vagina. The patient and her husband brought suit, charging that in performing the operation the physician carelessly and negligently cut the bladder, making a large hole in it, through which the leakage occurred. All of the witnesses on both sides of the case agreed that a hole might have been made accidentally by the physician in operating, or by unavoidable infection incident to the operation, or by infection independent of the operation, or by sloughing due to the natural trauma incident to the operation, or through other unavoidable causes. The case was tried, however, in harmony with the complaint, on the theory that the physician, in performing the operation, carelessly cut the wall of the bladder. The jury returned a verdict in favor of the patient. The physician thereupon moved for judgment in his favor, nothwithstanding the verdict. His motion was granted, and the patient appealed to the Supreme Court of Washington.

It may well be stated at the outset, said the Supreme Court, that the doctrine of res ipsa loquitur (the thing speaks for itself) does not apply to an action such as this, and the mere fact that a bad result has followed an operation is not of itself evidence of negligence. The only testimony in the record, said the court, indicating that the physician might have cut the wall of the bladder was what purported to be an admission by the physician, to his patient, concerning which she and her husband testified. The consensus of medical testimony, however, was that the history of the patient during the seven or eight days immediately following operation, during which period there was no escape of urine from the vagina, showed conclusively that the bladder was not punctured during the operation. All of the medical witnesses on both sides agreed that in an operation such as that to which the patient was subjected in this case it was necessary to peel as close to the bladder as it was possible to do without injuring the bladder wall. Two physicians who assisted in the operation, the nurse, and the physician who operated testified that the wall of the bladder was not cut at that time. The consensus of all the medical testimony was to the effect that a vesicovaginal fistula might follow a hysterectomy for cancer, and that the fact that it does follow is no evidence of lack of skill in performing the operation. The Supreme Court could find no evidence in the case that would justify the jury in finding that the bladder was cut during the operation, and that was the theory on which the complaint was based and on which the case was submitted. All charges of carelessness and negligence in treatment after the operation had been withdrawn before the case was submitted. As the Supreme Court could find no evidence to substantiate the charge that the bladder was cut during the operation, it affirmed the judgment of the trial court in favor of the physician, notwithstanding the verdict of the jury in favor of the patient.

Liability for Physical and Mental Suffering

(Georgia Power & Light Co. v. Haskins (Ga.), 151 S. E. 668)

The plaintiff, Haskins, went to the hospital to be confined. On being informed that a cesarean operation was necessary, she requested that her appendix be removed in the course of the operation, as she was suffering from appendicitis and had been suffering from it for some time. The hospital was lighted by electricity supplied by the defendant, the Georgia Power and Light Company. After the child had been removed and before the removal of the appendix, the company, without notice or warning, suddenly extinguished the lights, and service was not reestablished until forty-five minutes later. The lamps and flash-lights that were used in the interval of darkness were not sufficient to enable the operating surgeons to remove the patient's appendix, and since they did not know how long the electric lights would remain extinguished, they closed the wound without removing it. The inadequacy of the substituted lighting retarded the tying of the bleeding vessels and thus caused unnecessary loss of blood and consequent weakness. The plaintiff sued the electric light company, alleging that she had suffered much pain as a result of its negligence and carelessness; that she had suffered continuously from appendicitis since the operation; that, as a result of the loss of blood and the weakness produced by the operation, she had not sufficient physical strength to undergo another operation; and that she was informed by physicians that she would continue to suffer from appendicitis for the remainder of her life. Judgment was awarded in her favor, and the defendant appealed to the Court of Appeals of Georgia, Division No. 2.

A line of Georgia cases, said the Court of Appeals, has established the rule that where the breach of a duty consists only of a negligent failure to do some act, and that breach results in physical and/or mental pain and suffering, there can be no recovery of damages unless there is an accompanying physical injury: *Chapman* v. *Western Union Telegraph Co.*, 88 Ga. 763, 15 S. E. 901, 17 L. R. A. 430, 30 Am. St. Rep. 183; *Seifert* v. *Western Union Telegraph Co.*, 129 Ga. 181, 58 S. E. 699, 700, 11 L. R. A. (N. S.) 1149, 121 Am. St. Rep. 210; *Southern Bell Telephone and Telegraph Co.* v. *Reynolds*, 139 Ga. 385, 77 S. E. 388, 389. The present case is controlled by the decision in the Reynolds case, cited above. There the plaintiff claimed that she had been bruised, contused and lacerated, that she had hemorrhages and endured great physical pain and mental anguish and that her health had been greatly and permanently impaired. All this, she claimed, resulted from the failure of the telephone company to respond to the calls of her husband when he attempted to summon a physician for her when she was about to give birth to a child, with the result that the child was born without the presence of medical aid. There the court held that no cause for damages was set out in the petition, as, in the opinion of the court, there was no showing of a physical injury. In the present case the only ill consequence tending to indicate physical injury alleged to have been suffered by the plaintiff was the unnecessary loss of blood as she remained bleeding, wounded and helpless for several minutes. In the court's opinion, apparently, this was not a physical injury and the judgment of the lower court was accordingly reversed.

An Osteopath as a Legally Qualified Physician

(State ex rel. Walker v. Dean (Wash.), 284 P. 756)

In the State of Washington, under a law enacted in 1907, no one other than "a legally qualified physician" can be lawfully appointed as the city health officer of any incorporated city or town, except in cities of the first class. A physician so appointed holds office until January 31 of the year following that in which he is appointed or until his successor is appointed and qualified. When this law was passed, the laws of the state made no provision for the licensing of osteopaths. Not until two years later was a law passed providing for the issue of licenses to practice osteopathy (Laws of 1909, chapter 192, p. 677). Ten years later a law was passed (Laws of 1919, chapter 4, page 4) providing for the appointment of a board of osteopathic examiners, to conduct examinations of osteopaths and to issue licenses to practice osteopathy and to practice surgery. The statute required that persons licensed under it identify themselves as osteopaths by using the word "osteopathic" before the word "physician" or the word "surgeon," wherever either word appeared on their cards, signs, letter-heads, envelops and bill-heads.

Notwithstanding the requirements of the law that the mayor appoint "a legally qualified physician" as city health officer, the mayor of Ellensburg, Jan. 1, 1929, appointed a licensed osteopath to that office. The incumbent, a licensed physician who held the office, refused to vacate it in favor of the osteopath. The osteopath thereupon brought suit to establish his right to the office, basing his claim on the contention that he was "a legally qualified physician" within the meaning of the law, at the time of his appointment. The trial court decided the issue against the osteopath, and he thereupon appealed to the Supreme Court of Washington.

The Supreme Court, in the absence of any definition of the word "physician" in the laws of the state, quoted with approval a definition in Webster's New International Dictionary, "a person skilled in physic, or the art of healing." It is clear, said the Supreme Court, that a regularly licensed osteopath is a physician, within the broad or general definition of the word. The respondent, the physician who was contesting the right of the osteopath to the office, pointed out, however, that in 1907, when the law was enacted that limits the employment of health officers to "legally qualified" physicians, there was no law under which an osteopath could legally qualify to practice in the state. The court admitted that osteopaths were not within the contemplation of the legislature when, in 1907, it enacted the law. The osteopathic appointee contended, however, that the act of 1907 must be construed, not in relation to conditions as they existed when the law was enacted, but in the light of conditions as they existed at the time of his appointment. The court yielded to that contention and refused to follow the rule requiring the interpretation of statutes in the light of conditions existing at the time of their enactment, saying:

> The statute providing for the appointment of city health officers and stating the qualifications for such officials uses general terms. The act does not attempt to define the words which it uses in prescribing the qualifications which an appointee must possess, and, for the definition of the term used, reference must be had to general laws. This is not an instance in which a statute names several classes of eligibles, and because thereof classes not specifically named are deemed excluded. Such a rule of statutory construction is not applicable to the case at bar. . . .
>
> We are convinced that in construing section 6092, supra, in so far as the same prescribes qualifications for city health officers, reference must be had to the laws in force at the time an appointment thereunder be made, and that the inquiry is not governed by those laws which were in force at the time the act was passed.

Admitting that the osteopath was not under the law a physician in the broadest sense of that term, the court held that he was a "qualified" physician and that he was "a legally qualified osteopathic physician." In the judgment of the court, he was "a legally qualified physician" within the meaning of the statute and therefore qualified for appointment as a health officer.

Insanity: Arrests Without Warrant.—An insane person may be arrested and detained without legal process only when it is reasonably necessary, and a state of mild insanity does not make arrest and detention reasonably necessary. If, however, it appears that a person is dangerously insane, so that he is an immediate menace to himself or others, if allowed to be at large, it is then permissible for any person—whether an officer or not—to arrest the insane person without process and to detain him until proper process can issue. Where an officer arrests a person on suspicion of insanity, without first filing a complaint and obtaining an order of court for the arrest, he can, if he is sued for false imprisonment, justify his action only by showing by a preponderance of evidence that he had reasonable ground to believe, and did believe at the time, not only that the defendant was insane, but that he was in such a condition that it would not be safe to delay his arrest until proper process could be obtained.—*Christiansen v. Weston (Ariz.), 284 P. 149.*

Evidence: Cause and Effect.—Neither expert witnesses nor the jury may be turned loose to conjecture what may by some possibility result from given conditions. The verdict must be confined to what is reasonably probable. The verdict must be based on evidence that shows with reasonable probability that the injury will produce the effect attributed to it.—*Galveston Ry. Co. v. Powers (Texas), 101 Texas 161, 164, 105 S. W. 491, 493.*

Society Proceedings

COMING MEETINGS

American Society of Tropical Medicine, Cleveland, December 27-30. Dr. Edwin Peterson, U. S. Naval Hospital, Washington, D. C., Secretary.

American Student Health Association, New York City, December 29-30. Dr. D. F. Smiley, Cornell University, Ithaca, N. Y., Secretary.

Radiological Society of North America, Los Angeles, December 1-5. Dr. I. S. Trostler, 25 East Washington Street, Chicago, Secretary.

Society of American Bacteriologists, Boston, December 29-31. Dr. James M. Sherman, Cornell University, Ithaca, New York, Secretary.

Southern Surgical Association, Lexington, Ky., December 9-12. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.

Western Surgical Association, Kansas City, Mo., December 5-6. Dr. Frank R. Teachenor, 306 E. Twelfth St., Kansas City, Mo., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Varicose Vein Injecting Needle. R. L. Schulz, Los Angeles.—p. 746.

Fracture of Neck of Femur.—Eighty-six consecutive fractures of the neck of the femur are analyzed by Wilson. Thirty-three of these patients are dead, twenty-eight having died in the hospital and five after having been discharged from the hospital. Fourteen patients died from cardiovascular disease and nephritis; eight died from bronchopneumonia. Fibrinous pericarditis, lung abscess, cirrhosis of the liver and pyelonephritis each accounted for one death. Three patients died suddenly after reduction of fractures. These deaths were attributed to coronary occlusion or pulmonary embolus. One patient died as a result of a ruptured bladder due to the injury. The cause of death was not recorded in three cases. Sixty-two patients were treated by the Whitman method, seven by extension, three by the Championier method, and fifteen received no treatment. Of the sixty-two patients treated by the Whitman method, eight died during the treatment. The one patient between the ages of 21 and 30 recovered with bony union; in two patients between 31 and 40 there was healing by bony union; and in the two patients between 41 and 50, there was healing by bony union and in one there was nonunion. The percentage of nonunion increases with advancing years. Not one of the seven surviving patients between 71 and 80 showed any signs of repair. In the three surviving patients treated by extension, healing by bony union occurred in one; this was an accidental fracture that occurred during the manipulation of an arthritic hip. The patients classified under the heading of no treatment refused to submit to the measures recommended or were too feeble for surgical intervention. In only two of the fifteen cases was the period of hospitalization survived, with termination in nonunion. Two patients were treated by the method of Championier, mobilization and massage, and both were failures.

Chemical Adjuncts to General Anesthesia.—Examination of some of the possible chemical adjuncts to anesthesia by Leake indicates the need of an extended critical pharmacologic and clinical evaluation of the various agents proposed for preanesthetic hypnosis or metabolism regulation, and for postanesthetic complications. Such an evaluation should be made in the light of present physiologic conceptions and the objects of anesthesia. He avers that only such chemical adjuncts to anesthesia, and only such anesthetic agents, should be used as contribute to, or disturb the least, the best physiologic condition of the patient.

Tribrom-Ethanol as Preoperative Narcotic.—Wood reports her experience with the use of tribrom-ethanol in twenty-five cases. Most of the patients had had previously bad surgical experiences and dreaded this particular operation greatly. All fear of the operating room was eliminated. Even though some of the patients did not actually fall into a deep sleep, they remember nothing after the injection of the drug. There was a deeper relaxation of the patient than with other usual preoperative drugs. In the patients when ether was used with tribrom-ethanol, only a small amount was needed to maintain the proper level of anesthesia. When nitrous oxide-oxygen was used, a high percentage of oxygen could be maintained and the patients kept pink, while they were sufficiently relaxed for gallbladder, gastric and pelvic surgery, and only two patients required the addition of ether to the nitrous oxide-oxygen sequence. Because tribrom-ethanol does not affect the heart, and because a high percentage of oxygen can be used in nitrous oxide-oxygen mixture, and the patients are never cyanosed, it can be of great value in anesthetizing thyroid patients and patients with myocardial damage. Great care must be used in preparation of the dosage of the drug. With the dosages used, no untoward effects were noted on the blood pressure or respiration. The patients were unanimous in agreeing that it was the best surgical experience they had ever had.

Syphilitic Kidney.—In the urinary examination of 350 patients with syphilis, no definite instances of syphilitic nephritis in which improvement occurred under treatment were discovered by Bancroft. Neoarsphenamine treatment was followed by albuminuria in 3 per cent of 350 adult patients. Neoarsphenamine treatment was followed by albuminuria in 12 per cent of twenty-eight congenital syphilitic patients. Albuminuria occurred in 6 per cent of thirty-three syphilitic patients in whom dermatitis occurred during arsenical treatment.

High Carbohydrate-Low Calory Diet in Diabetes Mellitus.—Rabinowitch describes his experiences with a diet of high carbohydrate-low fat content in the treatment of diabetes mellitus. He says that, provided the fat content is kept low and the caloric value is within the minimum requirements, it is possible, in the majority of cases, to make the diet of the diabetic patient quite attractive even without the use of insulin. Where insulin is necessary, the dosage and frequency of administration is less than with diets ordinarily in use. A practical advantage of this form of treatment is that special articles of food, such as bran muffins and gelatins, are not necessary. Two characteristic metabolic features associated with these diets are (*a*) low plasma cholesterol and (*b*) nitrogen retention in the early stages. The diets contain between 50 and 55 Gm. of fat only and if the patient adheres to the following simple rules this amount cannot be exceeded: (*a*) Only one egg is allowed at breakfast. (*b*) Bacon, fatty meats and fish, and cream are forbidden. (*c*) The amount of butter is confined to about 10 Gm. at each meal. (*d*) Half a glass (about 4 ounces) of milk is allowed at each meal. (*e*) The total amount of meat or fish allowed for lunch or dinner is not more than 45 Gm. (1½ ounces) and it must be very lean. Fruits and vegetables, generally classed as 5, 10 and 15 per cent, are now included in one list for two reasons: (*a*) the relatively small amount of carbohydrate in the fruits and vegetables compared to the total amount allowed in the diet, and (*b*) the results of recent analyses of these food materials. The number containing 15 per cent or more carbohydrate is so small that, if the rule of varying the articles daily is followed, accidental ingestion of excess carbohydrates is avoided. The remaining part of the diet is bread and the amount the individual is allowed depends on his caloric requirements. He may receive nine, ten, eleven, twelve or more slices of bread each day. Each slice of bread added to this diet increases it by approximately 18 Gm. of carbohydrate, 3 Gm. of protein, 0.5 of fat and 70 calories. Bulk, if lacking, may be met by the use of fruits and vegetables of practically no food value. An interesting experience, unknown in the past with diabetic patients, is that, if the energy requirement is much greater than 1,800 calories, the diet may reach the point at which the patients complain of too much bread. In this case, the different kinds of 20 per cent fruits and vegetables, such as bananas, potatoes and the breakfast cereals, may be substituted for the bread.

Anesthesia for Operations on Gravid Uterus.—Featherstone is convinced that, by a wise choice of method, the anesthetist may be able to offer valuable help to the obstetrician and to the gynecologist. In the more severe procedures, gas-oxygen is the best agent for general anesthesia. Spinal analgesia has an important place in the technic of cesarean section.

Value of Tests of Liver Function.—Experience with liver function tests, as applied to a considerable group of patients suffering from various disorders, has convinced Piersol that the three most practical and clinically useful tests are (1) the retention of the dye bromsulphalein; (2) the estimation of the serum bilirubin, particularly the determination of the icterus index, and (3) the occurrence of urobilinogen in the urine. The retention of bromsulphalein is not an early indication of liver dysfunction. The degree of retention is a helpful indication of the extent of liver damage. When dye retention occurs, other liver functional tests are also positive. The estimation of the serum bilirubin is a more useful test of liver function, since it frequently indicates the presence of a latent icterus before liver disorders can be recognized by clinical signs, and the persistence of bilirubin in the blood after all other evidences of liver disease have disappeared. An increase in the urobilinogen is the most delicate test of impaired function. Urobilinogen is increased even when damage to the liver parenchyma is exceedingly slight. It is persistently increased so long as any residual hepatitis remains, and it is the one test which has been positive in a certain number of cases in which liver disease was suspected but could not be proved clinically.

Simple Method of Artificial Feeding in Infancy.—Wright and Geddes assert that it is perfectly safe to feed normal babies during the first year by appetite on lactic acid whole milk 20 ounces (600 cc.) with the addition of 2 ounces (60 cc.) of 50 per cent corn syrup, at four hour intervals, five feedings in the twenty-four hours, and for exactly twenty minutes at each feeding, boiled water being offered between feedings and the accessory food factors supplied in adequate amounts. Furthermore, they are inclined to believe that some such simplified feeding is safer to place in the hands of the busy general practitioner than one that requires to be modified at regular intervals.

Administration of Iron.—Proprietary preparations are often more palatable and are consequently preferred by patients, yet a physician recommending these proprietaries has no assurance that they contain adequate amounts of iron, or even the amounts that they are supposed to contain. Consequently, a study of combinations of the pharmacopeial preparations of iron and of flavors has been undertaken by Henderson and Sweet with the object of presenting certain simple and palatable recipes. They recommend the following simple iron mixture: iron and ammonium citrate, 5 grains (0.3 Gm.); compound tincture of lavender, 5 minims (0.3 cc.); syrup, 15 minims (0.9 cc.); sufficient water to make 1 ounce (30 cc.). For the tincture of lavender an equal quantity of liquid extract of liquorice may be substituted if the patient likes liquorice, or some 15 minims (0.9 cc.) of compound tincture of cardamom. If the physician has a diabetic patient or a child to whom he does not wish to give sugar, the prescription may be written thus: iron and ammonium citrate, 5 grains (0.3 Gm.); compound tincture of lavender, 5 minims (0.3 cc.); gluside, 1/10 grain (6 mg.); sufficient water to make 1 ounce (30 cc.). Either liquorice or cardamom may be substituted for the lavender, or 15 minims (0.9 cc.) of glycerin may replace the gluside, though the mixture is then not quite so palatable. To either of these prescriptions arsenic, in the form of arsenical solution, may be added: iron and ammonium citrate, 5 grains (0.3 Gm.); arsenical solution, 2 minims (0.12 cc.); compound tincture of cardamom, 5 minims (0.3 cc.); syrup, 15 minims (0.9 cc.); sufficient water to make 1 ounce (30 cc.). If the physician desires to use a laxative with the iron, the most agreeable form in which it may be added is as sodium sulphate, which has not the unpleasant bitterness of magnesium sulphate. In this case, liquorice with syrup is much the best flavor to use: iron and ammonium citrate, 5 grains (0.3 Gm.); sodium sulphate, 20 grains (1.3 Gm.); fluidextract of glycyrrhiza, 5 minims (0.3 cc.); syrup, 15 minims (0.9 cc.); sufficient water to make 1 ounce (30 cc.). If the dose of sodium sulphate must be increased to 30 grains (2 Gm.), the total quantity must be increased to 2 drachms (7.5 cc.) and then the liquorice may be increased to 10 minims (0.6 cc.). Bitters are often given with iron. Only three bitters need to be considered, quassia, calumba, and strychnine or nux vomica. Of these strychnine or the tincture of nux vomica is the most pleasant, and calumba the least agreeable. Five minims (0.3 cc.) of the tincture of any of these bitters may be added to the foregoing prescription. With nux vomica the mixture will not be at all disagreeable to most persons. Strychnine has the further advantage that it tends to increase the reflex excitability and muscle tonus that are often recognized by patients as a sense of fitness. In the following prescription, its bitterness is almost completely disguised: iron and ammonium citrate, 5 grains (0.3 Gm.); solution of strychnine hydrochloride, 5 minims (0.3 cc.); fluidextract of glycyrrhiza, 5 minims (0.3 cc.); syrup, 15 minims (0.9 cc.); sufficient water to make 1 ounce (30 cc.). Again, bromides in 5 or 10 grain (0.3 or 0.65 Gm.) doses may be added to the foregoing preparations without changing the flavor, if sodium bromide is used. The most palatable iron preparation they know is based on an old fashioned prescription containing solution of ferric chloride, aromatic spirit of ammonia and syrup, but this is greatly improved if written thus: solution of ferric chloride, 45 minims (2.8 cc.); solution of potassium hydroxide, 3 drachms (11 cc.); ammonium carbonate, 2½ grains (0.15 Gm.); tincture of lemon, 7 minims (0.4 cc.); spirit of nutmeg, 7 minims (0.4 cc.); syrup, 3 drachms (11 cc.); sufficient water to make 1 ounce (30 cc.). A dose of 1 drachm (4 cc.) contains approximately 5½ minims (0.3 cc.) of solution of ferric chloride. To this preparation, arsenical solution or bromides, or sodium sulphate, may be added, but not strychnine in any form. The order in which the ingredients are mixed is important. The ferric chloride and syrup should be mixed together, and then to this is added with stirring the caustic potash, dissolved in about half an ounce of water. The mixture is well stirred and the ammonium carbonate added with stirring. The mixture gradually darkens and any precipitate disappears. The other ingredients are then added. The dosage of iron in these prescriptions has been so chosen that the physician can readily double the amount by doubling the dose. In many cases, a change in relative amount of the flavoring ingredients will make an appreciable change in the flavor of the mixture.

Thyroparathyroidectomy on Gastric Disease.—Patients with chronic gastric or duodenal ulcer present a hyperirritability somewhat suggestive of latent tetany. To investigate a possible relationship, a thyroparathyroidectomy was performed by Winkelstein and Ziegler in sixty dogs and four cats. Twenty dogs and three cats died in tetany without the administration of parathyroid extract. Twenty-four dogs that had received parathyroid extract for two weeks only died in tetany. Nine dogs, after two weeks of parathyroid extract administration, lived normally without it, and in these an ulcer excised in the stomach at the incisura angularis was found healed in from ten to ninety-two days. The authors conclude that a circular gastric defect, 5 cm. in diameter, extending down to the serosa, in the lesser curvature at the incisura angularis heals completely in approximately one to two months in an animal in whom a thyroparathyroidectomy has previously been performed. Apparently, neither a thyroid insufficiency nor a latent tetany interferes with the healing of a gastric lesion in the dog or the cat.

Creatinuria in Tuberculosis.—Examination of the urine of fifteen patients done by Thompson indicates the presence of creatinuria in pulmonary tuberculosis, febrile or otherwise. Repeated analyses demonstrated not only a fluctuation in the creatine output over a period of time but a variation in the total creatinine production as well. Creatinuria may not exist in all cases or in all stages of the disease, but its omission is rare. The cause of this urinary abnormality is undetermined, but since it persists after the disease is arrested Thompson suggests that it may be due to and may be a measure of certain tissue destruction during the active phase. The phenomenon of creatinuria in tuberculosis is not confined to man.

Chronic Strophanthin Poisoning.—Two cases of strophanthin poisoning are recorded by Hyman and Lowen; the first is one of acute poisoning while the second is one of chronic self-administered strophanthin overdosage. In both cases, disturbances of cardiac rhythm occurred; these disturbances were extrasystolic in origin and represented a state of hyperirritability engendered in the myocardium as the result of this drug. Withdrawal of the strophanthin preparation resulted in prompt clearing up of the cardiovascular disturbances. The second case is interesting in that it presents an unusually long history of self-administration of strophanthin over a period of four and one-half years, during which time about 300 grains (20 Gm.) of the drug was taken. The withdrawal of the drug was accompanied by a reduction in the number of ectopic points from which the extrasystoles arose; this reduction produced certain unusual disturbances of rhythm. Examples of triphasic and diphasic rhythm are shown and the hemodynamic factors responsible for these phenomena are explained. The intravenous administration of dextrose did much to accelerate the return to normal sinus rhythm. The differential diagnosis of extrasystolic arrhythmia from multiple ectopic foci and auricular fibrillation may be impossible without graphic assistance; the importance of the correct diagnosis lies in the indications for digitalis therapy. Whereas digitalis is indicated in rapid auricular fibrillation, it is strongly contraindicated in the extrasystolic arrhythmia due to overdosage with strophanthin.

Hydatidiform Mole as Cause of Positive Reaction in Aschheim-Zondek Pregnancy Test.—A definite positive Aschheim-Zondek test was obtained by Fanz and Gault with the urine of a woman, three days after having expelled a hydatidiform mole. As there was in this case no actual fetal formation, with development of chorion and decidua only, the authors attribute the pituitary hyperfunction to the internal secretion of one or both of these cell proliferates. On examining the curve of pituitary secretion during amenorrhea of the mother they found the anterior pituitary hormone rising abruptly in amount during the first month, remaining more or less fixed during the next five lunar months, to fall gradually during the later four months and then more abruptly for a week following delivery. This curve is practically coincident with the development of trophoderm and its derivative, the chorion, and in its later half of declination is coincident with the disappearance of Langhans' cells (from the fifth month on). The decidual proliferate of the uterus can hardly be considered a producer of hormone to the anterior pituitary, owing to the fact that it is inherently maternal tissue from the start. It would seem that the anterior lobe of the hypophysis (pituitary body) acts as a cosecretor organ to the growing placental proliferate (possibly layer of Langhans), causing anterior pituitary activity rather than the cells of the fetus per se. As the patient gave no evidence of breast hypertrophy, it would seem that the pituitary hormone has no effect on the breasts of the female.

Effect of Barium Sulphate Meal on Intestinal Protozoa.—Seven persons infested with intestinal protozoa were examined by Andrews and Paulson following their routine barium sulphate meal for periods varying from three to ninety-eight days. The number of certain organisms diminished so that they could not be found for periods varying from none to twenty-three days subsequent to the barium ingestion. They ultimately reappeared; i. e., in no case did the administration of 8 ounces (250 Gm.) of barium sulphate effect an extermination of the organism.

Pharmacology of Brominated Oils.—Brominized esters of the fatty acids from cottonseed oil and brominized sesame oil were administered by Smith and Wikoff to rabbits intratracheally and intraperitoneally. The brominized esters of cottonseed oil were found to be the best for roentgenologic work from both an economical and a chemical standpoint. The oil is eliminated from the site of injection in rabbits within a week. Repeated doses of the brominized esters did not produce deleterious effects.

Abnormal Phenomena in Bell's Palsy.—Riddell relates his personal experiences. Having, from some *unknown cause,* been attacked with herpes zoster, exhibiting itself on the left side of the scalp, and accompanied—or, rather, preceded—by a somewhat violent neuralgia, Riddell soon found himself a prey to Bell's palsy. He developed a hiccup within a few minutes of taking codeine, which kept up almost continuously for three days and another drug was substituted. The facial paralysis of the left side set in in a few days; and in a short time, he found a curious state of both retinas—he never has muscae volitantes. Instead of the retina, when he closed his eyes, appearing *uniform and plain,* it would assume the appearance of a dark colored cloth, of a texture like a Harris tweed, and beautiful in its texture. This, after a time, say half a minute, would become a tartan with a perfectly distinct division into squares, and with a coloring that was not always the same. He was unable to recognize the clan to which the tartan belonged but was perfectly certain that it was not his own, the pattern being much more complicated. Then, sometimes but not always, the tartan would change to a brilliant brocade of gorgeous hues and so remain for a time, changing back again to the Harris tweed or the tartan. There was no regularity in the changes and none of them were subject to the will: they came and went in a whimsical manner. This phenomenon continued until the eyes were clear from all trouble, and then the old familiar plain background appeared again and has continued; no effort brings back the spectacle. Another curious circumstance was that, as soon as the palsy was established, Riddell felt as though the left side of the face were far removed; that it really was no part of him. The nose seemed to be the extreme right side of the head with the right eye just to the left. This also disappeared with the paralysis itself.

Coronary Disease in Diabetes Mellitus.—Blotner presents a clinical study of thirty-five fatal cases of diabetes with coronary artery disease. Coronary sclerosis has occurred in 45 per cent of all cases of diabetes that have come to necropsy in the Peter Bent Brigham Hospital. Coronary disease was found in 21 per cent of a nondiabetic group above the age of 40 years. Ten of the diabetic patients had no symptom referable to the heart before they entered the hospital for the last time. Twenty-five had more or less significant cardiac symptoms, lasting from several months to ten years before they came under observation, but most of them entered the hospital for varying complaints that were not related to the heart. Yet the chief cause of death in 43 per cent of all the series was directly attributable to heart disease. Cardiac infarction caused death in 10 per cent of seventy-seven fatal diabetic cases and in 23 per cent of thirty-five fatal diabetic cases with pathologic evidence of coronary sclerosis. Cardiac infarction is a not uncommon complication of diabetes and may be masked by the clinical picture of diabetic coma. Death from cardiac infarction occurred in three cases shortly after a rapid fall in blood sugar concentration following the administration of insulin. A sudden lowering of the blood sugar concentration by insulin may be dangerous for the elderly diabetic patient with vascular disease; such a patient is likely to have sclerosis of the coronary vessels as part of generalized arteriosclerosis. The sudden lowering of the blood sugar level by insulin may induce coronary thrombosis and a fatal outcome.

Interscapulothoracic Amputation.—The technic of interscapulothoracic amputation is described by Daland. Two cases are reported in which this operation has been done. The operation is indicated in traumatic and malignant conditions of the arm and shoulder in which simple disarticulation would be insufficient to remove the damaged areas. An appliance for reducing the deformity is illustrated.

Prevention of Colds by Vaccine Therapy.—Personal experience has convinced Murray that catarrhal vaccine as a preventive for head colds is uncertain as to results. The treatment might well be offered as a preventive treatment to persons unusually susceptible to head colds, after its limitations have been definitely explained. Any physician giving this vaccine treatment will be impressed with some of the results obtained and disappointed in other cases. In the group who have had the vaccine treatment for three successive years, the number of colds has been reduced from 245 to 95, a percentage gain of 61 per cent, and the average of four colds per person has been cut to 1½ colds per person. This reduction makes the treatment in industry economically sound. One would be safe in saying that the catarrhal vaccine as a preventive of colds seems to be helpful in 50 per cent of the persons taking it.

Separation of Nates by Adhesive Plaster During Operations for Sinus.—Bearse uses strips of adhesive plaster, from 2 to 3 inches in width, and long enough so that one end can be fastened to the operating room table. The other end is attached to the buttock to make traction. They are placed far enough up on the buttocks to insure firm adhesion but should not encroach too closely on the operative field. After the cyst or sinus has been excised and to aid skin apposition, the adhesive plaster is cut from its attachment to the table. The adhesive strips are completely removed from the skin after the completion of the operation.

Rickets in Infants in New Orleans.—In the series of cases studied by Crawford and Williamson, they found that cod liver oil administered daily from the tenth day of life did not prevent rickets, but there was a smaller percentage of infants affected in the group receiving the oil regularly than there was in the groups receiving it irregularly or not at all. They found rickets appearing more frequently in the male than in the female and the centers of ossification of the carpal bones developing later in the male than in the female.

Tumors Among the Insane.—Davidoff asserts that most recognized brain tumor cases exhibit some psychopathologic changes which, if analyzed by the neurologist and the neurosurgeon, might give some suggestion as to the localization of the growth. On the other hand, a certain small percentage of psychotic patients are suffering, undiagnosed, from cerebral tumors that could probably be recognized if the psychiatrist would keep in mind the possibility of such a lesion. These patients may be divided into two groups, (1) those with slowly developing symptoms chiefly of mental deterioration and few neurologic signs, and (2) those with a profusion of neurologic signs in addition to a rapidly disintegrating mentality. The first group usually have slowly growing tumors, meningiomas, for the most part. The second group prove to have rapidly growing gliomas, chiefly glioblastoma (spongioblastoma) multiforme. The diagnosis of tumor in the first group is often missed for lack of investigation of inconspicuous signs; in the second, for failure properly to evaluate the many obvious signs that present themselves.

Treatment of Arthritis "Rheumatism."—Shahon stresses the point that there is no specific treatment for arthritis as yet but several modes of treatment have been adopted by several workers in this field with marked appreciable results. The skilled use of physical therapeutic measures, massage, hydrotherapy, postural exercise, external heat, diathermy, chemotherapy and nonspecific protein therapy, such as typhoid vaccines and milk, have benefited many patients. The milk injection method is the most economical and simplest and insures in many cases marked improvement.

Are There Indications for Operations on Suprarenal Glands?—Crile concludes that indications for unilateral suprarenalectomy or, better, bilateral denervation of the suprarenal glands cannot be finally stated at the present time. In certain cases of residual hyperthyroidism, the symptoms seem to be completely controlled by division of the nerve supply of the suprarenals or by unilateral suprarenalectomy. In cases of intractable peptic ulcer, denervation of the suprarenal glands gives promise of good results. Whether or not these operations will have a wide application is still *sub judice*.

Nature of Icterus Neonatorum.—Goldbloom and Gottlieb review the work done by them in this field. They have been able to demonstrate that icterus neonatorum, which is present, whether visible or not, in all new-born infants, is hemolytic in origin. They have shown that this icterus is related to the destruction of a large excess of red blood cells in the infants' circulation and that the fragility of the red cells shows an increase in the first day or two of life, and a return to the adult normal at the end of the first week of life. The inefficiency of the placenta as a respiratory organ, coupled with the arterial-venous mixture in the fetal circulation, are regarded as at least two of the known factors that contribute to the development of the prenatal polycythemia. Finally, they have shown that, after having produced polycythemia in animals by reducing their oxygen supply, jaundice can be produced when the oxygen supply is returned to normal.

Treatment of Acute Syphilis with Bismuth Arsphenamine Sulphonate (Bismarsen).—O'Leary and Brunsting have had four years of experience in the use of bismuth arsphenamine sulphonate (bismarsen) in the treatment of syphilis, particularly of the acute phases of the disease. Of the 167 patients with acute syphilis who were started on treatment, sixty-four completed a series of at least thirty injections, but only thirty of these patients have been observed recently enough to warrant statistical study. Of these thirty patients, twenty-one have not shown evidence of clinical or serologic relapse, whereas nine have manifested neurorelapse in the form of asymptomatic neurosyphilis. Six patients with chancre whose treatment was started while the Wassermann reaction of the blood was still negative apparently are "cured." Of fourteen patients who presented seropositive primary syphilis when treatment was started, seven have withstood the test of observation and the condition of seven has relapsed in one form or another. None of the nine patients who presented asymptomatic neurosyphilis when first seen with the signs of acute syphilis manifested improvement in the condition of the spinal fluid. It is thus evident that the incidence of relapse, particularly in the nervous system, following the use of bismuth arsphenamine sulphonate is higher than with other systems of treatment previously used for acute syphilis. In those cases in which inunctions of mercury were used coincidentally, no material decrease in the incidence of relapse was noted. In a smaller series of cases in which treatment has been administered more recently, decreasing of the interval of time between the courses to two weeks, and giving a minimal of forty injections, there has not been as yet any obvious change in the results of treatment. The encouragement, drawn from the response in a limited number of cases, early in their experience with bismuth arsphenamine sulphonate, has not been substantiated by longer observation in a larger series of cases. That the drug has limited value in syphilotherapy is evidenced by the results of treatment in the seronegative stage of chancre. However, the frequency of neurorelapse has been sufficiently high to offset the results in this small group.

Infant Mortality in Southern States.—This study by Brooks shows a higher infant mortality rate in the Southern states from 1924 to 1929 than prevails in other states in the Union, and a higher infant mortality rate in the larger cities of each of the Southern states studied than in other cities of the Union selected at random and widely separated. The factors determining infant mortality rates are presented, and their bearing on conditions in the Southern states is shown. It is asserted that intelligent care is the chief factor in reducing infant mortality. A brief study of the work done in the well-baby clinics of Durham, North Carolina, is presented, showing a resulting decline in the infant mortality rate in that city since the establishment of these clinics.

Parental Blood Serum in Prophylaxis and Treatment of Measles.—Bivings and Dickson use serum instead of whole blood, because the latter is effective in only twice the dosage of the former. Their experience has taught them that comparatively large doses of serum are necessary, and to use twice the amount would be rather strenuous for the patient. The formation of a large discolored area under the skin following the use of whole blood also argues against its use. Their technic of preparation consists simply in withdrawing twice the amount of blood as serum is needed from a parent or other suitable donor who has a definite history of having had measles at some previous time. Infiltrating the skin over the vein and using a large needle prevents premature clotting and allows sufficient blood to flow out into a sterile container. It is then set aside for from twelve to twenty-four hours in a cool place. At the end of this time, the serum is easily withdrawn into a large syringe and injected subcutaneously between the scapulae, where there is much loose tissue and little pain or inconvenience to the patient. Of a total of 103 patients treated, 71 were given complete protection and 32 developed measles in a modified form.

Rare Human Tapeworm, Taenia Confusa.—A case of *Taenia confusa* of more than eleven years' standing is reported by Faust from a native white woman from Louisiana. Thi constitutes the fourth known infection with this tapeworm. Th case history evidence, suggesting raw beef as a source of infe tion, is confirmed by experimental feeding of a suckling calf, which a miliary infection of cysticerci of an "unarmed" tenia was observed three months after feeding. Faust concurs in Chandler's view (1920) that the cases of this infection are considerably more numerous than the few reports indicate, since this would be necessary in order to perpetuate the species. The identity of *T. confusa* and *T. bremneri* is highly probable.

Agranulocytic Angina.—In the case of agranulocytic angina presented by Rudner and Michelson, the characteristic clinical signs were present. All methods advocated as therapeutic agents, such as roentgen ray, frequent blood transfusions and leukocytic extracts, failed to bring about a cure in this case. The patient died.

Radium Treatment of Epithelioma of Skin.—Of 1,773 consecutive cases of squamous-cell epithelioma treated at the Radium Institute, London, Ward says 91 per cent of the hypertrophic type were apparently cured; 77 per cent of the flat type and 38 per cent of the deeply ulcerated type. Many of the last group were such that healing was out of the question, owing to extensive involvement of bone and cartilage.

Puerperal Sepsis.—Murray urges that there should be a larger proportion of fully trained nurses on the staff of maternity hospitals, especially for the nursing of suspect and septic cases. Clean and suspect cases cannot be nursed together; the former are endangered, and the latter tend to be neglected. The problem of isolation is one of great anxiety, as many maternity hospitals are quite unequal to the demand made on them. They were designed before the notification of puerperal pyrexia produced such an influx of febrile cases requiring hospital treatment, which at times tends to convert them into fever hospitals. The following would appear to be the minimum requirements of a modern maternity hospital: (1) an admission room for preliminary classification; (2) examination rooms and wards for (*a*) clean, (*b*) suspect cases, (*c*) cases of genital sepsis, and (*d*) cases of extragenital sepsis. Each of the four units should have its own labor ward and nursing staff.

Respiratory Complications Following Surgical Operations.—The statistics given by Aikenhead consist of 33,066 operations performed during the four years 1926-1929; 31,301 operations were under general anesthesia, and the remaining 2,765 were conducted under some form of local anesthesia. There were 55 respiratory complications with 23 deaths. Great care is exercised in excluding from operation patients with a cold or coryza, even if afebrile. More than half of this series received ether dropped on a thick cotton fabric supported by a wire frame; a mixture of two parts of chloroform with three parts of ether was added in any operation in which ether would not induce sufficient relaxation by itself. Nitrous oxide and ethylene were administered by McKesson machines; one in six would be a rough estimate of gas anesthesia. Postoperative ward treatment varied widely according to the individual clinician. The gravity of the operation ranged from excision of a sebaceous cyst, and brief dental extractions, to thousands of appendicectomies and herniotomies, and severe operations on patients with grave renal or cardiac conditions. The ages of the patients ranged from 4 days to over 90 years. Of the 55 patients with respiratory complications, 13 had sequels of a minor nature, 7 infarcts, and there were 6 cases of pleurisy; the remaining 42 suffered from pneumonic processes. These 42 cases included 9 emergency operations; 16 patients (including 7 of the previously mentioned) had marked elevation of the pulse, temperature and respiration at the time of operation. Nine patients were over the age of 60, and in 23 (more than half) the operation involved the gastro-intestinal tract, including herniotomies. Twenty-three of the 42 patients with major complications died, and at the time of operation 19 of these 42 had gross sepsis. Of these 19 patients with sepsis, 14 died (73 per cent). Twenty patients out of the 55 originally mentioned were first-class operative risks with 1 death; this may be compared with the 35 substandard patients with 22 deaths. In 1929, of 1,772 abdominal operations (excepting 242 thyroidectomies), there were 6 respiratory complications with 2 deaths; both patients who died were over the age of 70, and the operations were emergency ones. Aikenhead points out that, taking into consideration the number and gravity of modern surgical procedures, pulmonary complications following operations are less numerous than might be expected. He feels that careful selection of patients, and preoperative measures with equal attention to the matter of after-care, will keep the incidence of respiratory lesions down to the minimum, until such time as a definite cause is known for this dreaded operative sequel.

Influence of Lactation on Ovulation and Estrus.—Cunningham presents evidence to prove that there is no general correlation between the stimulus of sucking and the suppression of estrus, as is assumed by the theory of Crew and Mirskaia. This correlation occurs in the mouse and rat, the ferret, the rabbit and the Virginian opossum, but it is absent in the cow, mare, goat, pig and frequently, if not always, in the human species. The really significant correlation, he says, is between the suppression of estrus and the condition of the new-born young. In those cases in which estrus is inhibited the young are naked, immature, and kept for the greater part of the time enclosed in a warm nest in close contact with the mother. In the other cases in which estrus occurs during lactation, as in the cow and the guinea-pig, the young are born covered with hair and able to run almost at once. If the inhibition of estrus were due to the absorption of soluble substances by the mother from the bodies of the young, either from the mouths of the latter through the teats or from skin to skin, the correlation between the nidicolous immature condition of the young and the suppression of estrus during lactation would be explained, while on the theory of the stimulus of sucking, since this stimulus occurs in the cow as in the mouse, there is no reason for the difference between the two in respect of estrus during lactation. The case of *Didelphys* is especially important, for here the young are born after a gestation of only thirteen days in an early fetal stage of development and are transferred to the pouch, where they become permanently attached to the teats. The skin within the pouch is naked, vascular and glandular, and removal of the young from it has the same effect with regard to estrus as removal of the fetuses from the uterus in higher mammals. The stimulus of sucking maintains the process of lactation in all cases, whether in the cow or in the opossum, and it has been shown in the opossum and in the rabbit that the stimulus determines secretion, not in the whole system but in each gland individually; but it is improbable that it affects the occurrence of estrus.

Roentgenography in Direct Diagnosis in Addison's Disease.—Thompson urges that roentgen examination of the suprarenals should always be conducted in cases of Addison's disease, because when a positive result is obtained it gives the only direct evidence of disease of the suprarenals. A positive roentgen finding will be obtained only in those cases in which calcareous deposits are present in the tuberculous suprarenal glands. In those cases of Addison's disease which are due to simple atrophy of the suprarenals, no shadows are revealed in the roentgenograms taken of the suprarenal region. Recently he requested roentgenograms in two other cases of Addison's disease, but in both instances they gave negative results. In both cases, also, it was possible to examine the suprarenal glands at necropsy when the cause of the condition was found to be simple atrophy of the suprarenal glands. In those cases of suspected Addison's disease in which pigmentation is absent or for other reasons the diagnosis remains doubtful, a roentgen examination of the suprarenal glands may assist in the true interpretation of the condition.

Infective Granulomas and Streptococcal Infection.—Poynton and Moncrieff relate the case of a healthy child, aged 13 months, who, following a "bad cold," developed glandular enlargements that clinically bore a strong resemblance to those of Hodgkin's disease; postmortem examination revealed conditions, such as the nodules in the liver and the histologic appearances of the glands, that confirmed this diagnosis. At the same time there was evidence of a streptococcal infection, and it is on the relationship of this to the lymphadenomatous condition that the authors focus attention. They hold that if the streptococcal infection had been more virulent at the onset or the child's resistance less, an acute septicemia would probably have developed at once on her "cold" and, on the other hand, if her resistance had been greater the terminal acute features would not have been present but she would have died with cachexia and cardiac failure as in "ordinary" lymphadenoma. In other words, the child's tissues put up an unusual borderline type of response to streptococcal invasion, which closely resembled Hodgkin's disease if, indeed, it was not identical.

Spontaneous Pneumothorax.—In two of the cases reported by Symes-Thompson it was presumed that the pneumothorax was caused by the rupture of an emphysematous bulla, but no demonstrable generalized emphysema of the lungs was present in either instance. Pulmonary tuberculosis was not present in either of these cases or in the third case, in which the pneumothorax was a complication of asthma. The fourth case was one of pulmonary tuberculosis in which spontaneous pneumothorax developed while the patient was undergoing artificial pneumothorax treatment.

Desiccated Hog's Stomach in Pernicious Anemia.—Allerton's patient relapsed after treatment for eighteen months with liver extract, and subsequently recovered when desiccated hog's stomach had been added to his diet.

Impending Ischemic Contracture.—The case described by Nelson presented the classic signs of an impending ischemic contracture—namely, a supracondylar fracture occurring in a child, aged 9, a brawny induration in the arm which was gradually increasing, persistent severe pain, cyanosis of the hand, and limited voluntary flexion of the fingers. After exactly eleven hours a 4-inch longitudinal incision was made on the medial side of the front of the elbow joint. The skin was so tight that it appeared to split apart in front of the knife. The incision was continued through the deep fascia, which was as tightly stretched as the skin. A quantity of dark red fluid welled up from the incision, and after this fluid had been wiped away a small spurting artery, probably the anterior ulnar recurrent, was found in the depth of the wound and ligated. The fracture was inspected, and the position of the fragments seemed to be satisfactory. An examination of the median nerve and brachial artery was now possible. Distal to the elbow the artery was difficult to identify, owing to its great constriction, but on being traced upward both median nerve and brachial artery were seen to be nipped between the surfaces of the fracture. The fragments were gently levered apart and the artery and nerve released. The artery was intact and the pulse returned at the wrist; the nerve was flattened but did not appear to be torn. The margins of the incision could not be drawn together, and a gap of 1 inch remained. The induration in the arm disappeared within three days, and in ten days the limb had returned to its normal size. At no time did the fingers or wrist show any contracture. There was wasting and paralysis of the flexor and abductor pollicis brevis and anesthesia of the volar surface of the index finger. The discharge from the wound was serous and so copious that it soaked through all the dressings. The wound remained noninfected, granulated slowly, and at the end of seven weeks was covered with skin. The movements began to return after three months of complete fixation at 80 degrees flexion. All the muscles of the arm were functioning normally; the flexion and extension of the fingers were normal and the thenar muscles had recovered. There was slight anesthesia on the volar surface of the index finger. After twelve months the range of movement has been gradually increasing and is now about 50 degrees. There is full pronation and supination, and the child uses her arm as she would if it were normal.

Radium in Treatment of Cancer of Breast.—For operable cases Handley feels that the method of Keynes (extensive and prolonged irradiation by buried radium tubes), which has given him good early results, must be admitted to equal competition with ablational methods. When a patient asks him whether he advises operation or treatment by buried radium he usually offers her the choice, adding that if she has the investor's rather than the speculator's temperament she will choose operation combined with selective irradiation. He would not, however, give such freedom of choice to all patients. In patients advanced in years, and with myocardial degeneration or organic disease of the heart, a heavy dose of radium may cause irregular and rapid cardiac action, or pericarditis. A left-sided carcinoma in such a patient can be more safely treated by operation than by radium. Speaking on the use of diathermy in breast cancer, he says: The method represents not a mere optional variation in technic but a striking improvement. Its advantages depend mainly on three peculiarities of diathermic cutting: (*a*) It seals most of the small vessels as it cuts them and so minimizes loss of blood; (*b*) it divides nerves almost without stimulating them and leaves their exposed ends insensitive; (*c*) during the operation it supplies heat to the body generally and especially to those parts which are exposed for the purposes of the operation. The three principal causes of operative shock, namely, violent nerve impressions, loss of blood and loss of heat, are thus minimized.

Treatment of Carcinoma of Breast with Radium.—Keynes feels that the day has now passed when all radiologic treatment was kept strictly within the province of the radiologist. Interstitial radium treatment (as used by him) is a surgical procedure, though it requires knowledge of the properties and dangers of radium for its successful use. Further than this, it often needs to be combined with purely surgical treatment, and Keynes makes no claim that radium has superseded surgery. He believes, however, that radium is the treatment of choice as a first stage in the majority of patients. For those with "inoperable" tumors, it is the only possible treatment. For those with the earliest growths it is the preferable treatment, because the patient is restored to normal. For those with advanced but still operable tumors, no known form of treatment can be relied on to save the patient's life, because in most cases the disease has already passed beyond the local—that is, the curable—stage. On the whole there is less suffering for the patient with primary radium treatment than with operation. He reports on 130 patients with primary carcinoma of the breast treated with radium.

Radium Treatment of Cancer of Breast.—Cade discusses his experience with the Keynes plan of treating carcinoma. He says: The position of radium therapy in the treatment of cancer of the breast cannot be definitely assessed till five-year periods are available for operable cases. That radium can provide complete retrogression of the disease has been proved in numerous cases. The permanence of results is greatly enhanced by the two-stage treatment. Radium therapy as the first measure in the treatment of an operable case is entirely justifiable, and the earlier the case the better is the result. For inoperable cases and for recurrences, radium offers a great deal of palliation and cannot be equaled by any other method of treatment.

Modern Treatment of Carcinoma of Breast.—Fitzwilliams, too, is an ardent advocate of radium therapy of carcinoma. However, instead of leaving the needles in six or seven days on a single occasion as formerly, he now leaves them in for five or six days, then gives the patient one or two weeks' rest and reinserts them, but not in the same place. The gridiron is arranged differently this time, and the surrounding needles are placed between their former situations. Later, surface irradiation is given as usual. The patients wear a plaque of Columbia paste with radium applied to the outer side, for a time varying from two to four weeks according to the number of hours a day they wear it and their sensibility to radium, a well marked erythema with superficial desquamation being aimed at.

Aspects of Radium Treatment of Carcinoma.—Cheatle reports on cytologic examination of irradiated tissues. There is comparative freedom from the effects of irradiation of the normal epithelium, although it was in the area of 1 cm. round a needle containing 2 mg. of radium for eight days. The irradiations appear to have a specific action on the malignant cells. All the cells were within an area of 1 cm. of the source of radiation. A large proportion of malignant cells are not actually destroyed. Many of the undestroyed cells are so degenerated that they may not recover. There are other malignant cells which may either recover or may never become capable of multiplication, having lost their malignant character. It cannot be said that irradiation increased the number of lymphocytes, polymorphonuclears or macrophages in the irradiated area, since precisely similar pictures can be seen in unirradiated squamous epitheliomas of the lip. The type of degeneration induced by irradiation of the malignant cells is an unusual one. Abnormal mitosis has actually occurred during their irradiation.

Chilblains Treated by Melted Paraffin Wax Bath and Ultraviolet Rays.—The melted paraffin wax bath was introduced by the late Colonel Littlewood during the latter part of the war. Results of observations and tests have proved that this bath is of considerable therapeutic value in itself and also as a preliminary for massage and other treatment, and its properties make it an important factor in the armamentarium of, modern physical therapeutics. The bath used by Humphris is made of fire-clay 3 inches thick (this is necessary to prevent radiation of the heat); it is 6 feet long, with parallel sides, white glazed inside and over all; it is supported by four white glazed fire-clay pedestals, and has a stoneware draw-off tap, and is fitted up with a self-contained electrical heating apparatus and heat-regulating switch; this is fixed at the tap end of the bath and keeps the molten wax in circulation. The whole heating apparatus is enclosed in white enamel ironwork. Another bath of similar construction, but built vertically, is also used, and smaller baths for the limbs have also been constructed, but in these it is difficult to regulate the heat satisfactorily on account of their smaller capacity. Paraffin wax with a melting point of 120 F. is placed in the bath in large cakes and heated by two temporary coils of wire; when the wax is sufficiently heated, these may be removed and the bath heated at will by the permanent heaters. The patient remains with his hands or feet in the bath for about twenty minutes, at a temperature of about 120 to 130 F. At the end of this time the part under treatment is removed from the bath and allowed to cool. After two or three minutes the wax can easily be peeled off the limb. Other conditions besides chilblains which Humphris has found to respond to this treatment include neuritis, rheumatic and gouty joints, fibrositis, especially in and around small joints, scleroderma following old lymphangitis, cramp in the calf of the leg, intermittent claudication, eczema vesiculosum, phlebitis and Raynaud's disease. Slight mechanical irritants produce bullous elevations of the epidermis over the nodules, or doughy swellings, and those blister-like formations, filled with blood-stained serous fluid, are apt to break down and form atonic ulcers which heal with difficulty and present the commonly called broken chilblain. Here the ultraviolet rays are most useful, and with their use the abraded surface readily heals. The daily application of a mild dose of the rays soon stimulates the sluggish ulcer and promotes healing, and then the cure proceeds as in the unbroken variety.

Acute and Chronic Gastritis: Anatomy and Pathology. M. B. Dahl.—p. 761.
*Diagnostic Value of Xiphoid Pain. A. da Silva-Mello.—p. 808.

Diagnostic Value of Xiphoid Pain.—Da Silva-Mello shows that a painful point located at the xiphoid process is often an important pathognomonic symptom in lesions of the upper part of the abdomen, especially duodenal ulcers. This painful point is definitely localized directly over the cartilage and is the most objective of the abdominal points. It is easily discovered by a physician experienced in the technic of abdominal palpation. One of its chief advantages is that its intensity varies with the aggravations and ameliorations of the condition of the patient, which makes it a valuable guide in measuring the success of the treatment employed.

*Value of Dick Test. F. Coste, P. George and Yuen-Si-Tchong.—p. 237.
Hemorrhagic Periduodenitis with Splenomegaly. J. Caroli.—p. 239.
Professional Fluorism. A. Feil.—p. 242.

Value of Dick Test.—Coste et al. performed two series of experiments to determine the value of the Dick test. In the first series, 108 patients were given successive injections of the standard toxin. In the second series 91 patients were injected not only with the standard toxin but with other forms, especially erysipelatous toxins; also several patients were given a single injection of 100 skin units of the standard toxin. The results in the two series of tests were practically the same. In about half of the patients the reactions were either positive or negative to all the injections. In some the reactions were positive at first, then negative after from three to eight injections. In others (about one fourth of the total number) the results were wholly inconstant, shifting from positive to negative and back again. The Dick test cannot therefore be considered as an infallible proof of receptivity or immunity. It is merely a secondary element in the streptococcic theory.

Mucosal and Cutaneous Aurides in Chrysotherapy. F. Lebeuf and H. Mollard.—p. 1239.
*Emetine Treatment in Pulmonary Abscess. J. Fliederbaum.—p. 1242.

Arterial Pressure After Section of Spinal Cord.—Leriche and Fontaine show by operations performed on ten dogs that a high section of the spinal cord does not produce hypotension and vasodilatation in the limbs. When hypotension does follow the operation it is due to loss of blood and to surgical shock, which can be avoided by better operative technic. These results tend to weaken the theory of the supremacy of the bulbar vasomotor center, formerly considered as firmly established. At times, even when the operation has been successful and there was no immediate hemorrhagic condition or hypotension, a few days later a more or less marked hypotension is noted. However, the limbs present normal vascular reflexes produced by various stimuli, and the arterial tension soon becomes normal again. The authors attribute this phenomenon merely to the general physical weakness which necessarily follows a serious operation.

Albumin Content of Blood in Arterial Hypertension and Hypotension.—Dumas et al. determined the albumin content of the blood in a number of patients suffering from arterial hypertension or hypotension by the azotometric method of

Achard. They observed that hypertension is accompanied by hyperalbuminosis and hypotension by hypo-albuminosis. However, the proportion of serine and globulin is not constant. In cases without particular complications the variations in the albumin content affect serine and globulin almost equally, so that the quotient remains the same. In more severe cases, however, such as hypotension accompanied by fever, there is augmentation or absence of diminution of the globulin, which lowers the quotient. Globulin, therefore, seems to be the resistant form of the albumin of blood serum, and the lowering of the quotient is a defense reaction that should be considered as a symptom of grave import.

Emetine Treatment in Pulmonary Abscess.—Fliederbaum used emetine in the treatment of eighteen patients with pulmonary gangrene and fifteen patients suffering from pulmonary abscesses. The intramuscular method of injection proved most successful because it eliminates the sudden shock, lowering of the blood pressure, and other complications caused by intravenous injection as well as the aseptic abscesses sometimes produced by subcutaneous injection. The emetine treatment is often helpful when neoarsphenamine has produced no results. On the other hand, the action of emetine does not take effect for several days, and it is sometimes necessary to use neoarsphenamine at first as a means of attack and then employ emetine to bring the cure to a successful conclusion. The therapeutic effect of emetine is due to its bactericidal action on the flora of the abscess or gangrene, also to the fact that it incites the organism to a more active struggle with the pathogenic bacteria. Its chief advantage over neoarsphenamine is that the latter has a more immediate drastic action, which is dangerous at times.

Revue de Chirurgie, Paris

68: 85-151 (April-May-June) 1930

*Drainage of Choledochus Through Gallbladder in Chronic Pancreatitis. P. Santy, P. Mallet-Guy and V. Pasquier.—p. 85.
*Technic of Fixation of Fractures of Neck of Femur by Means of Screws. R. Bloch.—p. 105.
*Arthrodesis in Tuberculosis of Shoulder. R. Massart.—p. 112.
Intraperitoneal Hemorrhages of Ovarian Origin. M. Haller.—p. 132.

Drainage of Choledochus Through Gallbladder in Chronic Pancreatitis.—Santy et al. believe that drainage of the choledochus through the gallbladder is the operation of choice in the treatment of chronic pancreatitis with jaundice. A cholecystogastrostomy is sometimes advisable, especially in cases in which the diagnosis of chronic pancreatitis is not certain and the existence of cancer is suspected. A cholecystostomy is efficacious in about 50 per cent of the cases; in about 25 per cent, however, a fistula persists, and in 25 per cent the operation is entirely unsuccessful and causes disturbing, though not dangerous, postoperative complications. Kehr's operation, while it usually gives good results, often leaves dangerous ulcers and therefore is not recommended for general use. Drainage of the common bile duct through the gallbladder, however, drains the duct as well as Kehr's operation does and is quite as safe. The authors recommend this method for the majority of cases. It consists of a choledochotomy with direct drainage of the common bile duct by placing a Kehr's tube in the interior of the hepatic duct. The gallbladder and cystic duct, which are usually dilated, form a protective sheath for the exterior branch of the tube. The gallbladder is opened at the bottom and through the opening a tube that has been introduced through the incision in the choledochus and into the cysticus is grasped with forceps and drawn into place.

Fixation of Fractures of Neck of Femur by Means of Screws.—Bloch advocates the use of a simple operative technic that can be performed without any special apparatus or instruments, in contrast to Delbet's method. The reduction of the fracture is made by forced abduction and internal rotation; the abduction should be carried to a maximum, with the summit of the greater trochanter pressed on the iliac bone. This is the same position that is used in the Whitman method. All that remains then is to insert a wood screw, about 2 cm. shorter than the roentgenographic image of the bone, to hold the neck of the femur in position. The best point to insert the screw seems to be slightly below the trochanteric crest and to the rear, which allows it to become securely lodged. The bone may be pierced with a gimlet, a drill or a trepan; Bloch prefers to use a Doyen trepan. The tool is driven into the neck of the femur until it meets a tissue of greater resistance. It is then removed and the screw itself is inserted; usually only a few turns are necessary to fix it securely in place. Because of the simplicity of the method, such operations may be employed much more extensively than was possible in the past. The author recommends the use of spinal rather than local anesthesia.

Arthrodesis in Tuberculosis of Shoulder.—Massart shows that a scapulohumeral ankylosis is not an undesirable operative result since it causes little inconvenience to the patient. A resection, therefore, that results in ankylosis is not unsuccessful if it has succeeded in eliminating the infected parts of the bone. Likewise arthrodesis, skilfully performed, is an extremely valuable method of treating tuberculous scapulalgia. The author prefers an incision from above both in simple resection and in arthrodesis, since this is the most direct and certain and the least vascular course and the one that best exposes the glenoid cavity and the upper extremity of the humerus. He uses multiple osteoperiosteal grafts, usually in the form of an arc from one bone to the other, to fill the cavity left by the removal of the infected portions of the bone. The wound is sutured without drainage, and the shoulder and arm are immobilized in a cast for at least two months; as an additional precaution a small plaster-of-paris spica should be used on the shoulder for another two or three months.

Posttraumatic Malacia of Carpus: Pathogenesis. Mutel and Gérard.—p. 531.
*Methylated Antigen in Treatment of Surgical Tuberculosis. B. Blankoff.—p. 538.

Treatment of Surgical Tuberculosis with Methylated Antigen.—Blankoff describes thirty-seven cases of surgical tuberculosis in which methylated antigen was used. Twelve of the patients were cured, eleven showed definite amelioration, ten did not respond to the treatment, and four were still under treatment when the article was written. All the cases in which the treatment was used were longstanding ones in which other methods of treatment had failed. The twelve cures and eleven ameliorations obtained are, therefore, more significant than the ten failures. In addition to the classic method of injection, compresses were found to produce excellent results, especially when the lesions were superficial or easily accessible. A combination of antigen treatment with ultraviolet rays was also used successfully in several instances and materially aided rapid progress. The effects of the methylated antigen treatment are in general inoffensive, although there may be more or less painful local reactions lasting a few days. When the treatment is effective, suppuration always results; this is explained as a defense reaction in which the formation of antibodies produces a state of hyperleukocytosis in the centers of infection and thus aids the elimination of the infected portion of the bone. While the methylated antigen treatment is not always successful, it is proving itself to be a valuable aid in the treatment of surgical tuberculosis and the writer feels that it should be employed more extensively.

Pigeon Scabies in Human Beings. A. Schrafl.—p. 900.
Relations Between Glycemia and Alkali Reserve. R. Choisy, S. Djivanoff and Ceresole.—p. 900.

Pathogenesis of Pulmonary Edema.—Wolfer points out that pulmonary edema may have various causes. First he discusses the mechanical theory. Experimental investigation of this theory has proved that the purely mechanically caused edema occurs only in rare cases. During heart disease, pulmonary edema occurs seldom. However, there are other forms of pulmonary edema that are of mechanical origin; namely, ventilation edema and edema caused by changes in the thorax. The author further discusses inflammatory and toxic edema. The toxic edema may be due either to poisonous products of metabolism or to poisons that are brought into the organism from the outside, such as iodine, alcohol, morphine and particularly gaseous poisons. The condition of the nervous system is also an important etiologic factor in some forms of pulmonary ema. In animal experiments, pulmonary edema has been prod by division of the vagus nerve. The fact that pulmonary na has been observed after traumas of the brain and follow- inflammation of the spinal cord proves that disturbances in the central nervous system may likewise be significant in the ology of pulmonary edema. Not all forms of pulmonary ema can be traced to one etiologic factor; in many cases, everal causal factors are involved.

Influence of Weather on Thrombosis and Pulmonary Embolism.—On the basis of thirty-five case reports, Fritzsche shows that in some cases of thrombosis or of pulmonary embolism meteorological factors are involved.

Histogenic Defense Reaction of Uterus. A. Albanese.—p. 523.
*One Thousand Gynecologic Cases in Which Diathermy Was Employed. I. Büben.—p. 536.

Serodiagnosis of Pregnancy by Means of Sdrodowski Modification of Abderhalden Test.—On the basis of his observations, Segre concludes that the serodiagnosis of pregnancy as proposed by Sdrodowski may serve as a diagnostic aid for the diagnosis of pregnancy in view of its simple technic and because it is nearly always positive in the gravid state, though it hasn't a strictly specific value.

One Thousand Gynecologic Cases in Which Diathermy Was Employed.—Büben regards diathermy as a valuable therapeutic aid in many gynecologic cases and particularly in inflammatory disorders of the true pelvis, in which, in addition to effecting an improvement of the pain symptoms, there is sometimes a shrinking of the inflammatory tumor or even its complete disappearance. Other indications for diathermy are gonorrhea in women, especially if it is combined with other bactericidal treatment; also in bladder disorders. It may be employed also to increase the sensitiveness of the tissues to rays in the treatment of cancer; also for diagnostic purposes to decide whether or not an inflammatory tumor of the adnexa is operable.

Multiple Osteogenic Exostoses. A. Zagami.—p. 400.

Influence of Nervous System on "Taking" of Homoplastic Grafts of Striated Muscle.—Bartoli performed experiments with homoplastic grafts of muscular tissue in muscles. Such grafts had given negative results in the hands of other authors, who, however, had not taken the nerve supply of the muscles sufficiently into account. The author therefore tested the neurotization of the homoplastic grafts applied to rabbits and found in an early stage "taking" of the graft and attempts at regeneration on the part both of the graft and of the host. In turn, there were manifestations of degeneration of the muscular fibers and their transformation into connective tissue.

*Hepatotherapy and Function of Spleen. G. Izar and U. Polerà.—p. 1267.
Obliteration of Varicose Veins by Injection of Thrombosing Substances. G. Millul.—p. 1269.
Precocious Syphilitic Nephropathy. R. Rinaldi.—p. 1278.

Hepatotherapy and Function of Spleen.—Izar and Polerà present the first results of a series of experiments to determine the exact effects of hepatotherapy on the function of the spleen. The method employed was simply to count the erythrocytes in the blood before and after the administration of beef liver, beef and epinephrine. They observed that beef caused a diminution of erythrocytes while liver and epinephrine caused a marked increase. The effects of the administration of liver corresponded in every way with the already well known effects of epinephrine. Patients with diffuse fibro-adenia of the spleen who did not react to epinephrine did not react to liver. On the other hand patients with splenic tumors, which cause an intense reaction to epinephrine, showed a correspondingly marked hyperglobulia after the administration of liver. The authors are convinced, therefore, that the increase in erythrocytes produced by hepatotherapy has a distinct relation with the active contraction of the spleen, which subject they intend to discuss more fully in a later article. They include here a tabulation of the results obtained in eleven cases.

*Greater Resistance to Hypotonic Solutions as Shown by Erythrocytes Circulating in Capillaries of Skin as Compared with Those in Veins. A. Montanari.—p. 705.
Crossed Paralysis. A. Terzani.—p. 726.

Resistance of Erythrocytes.—Montanari studied the resistance of erythrocytes in the capillaries of the skin, as compared with the resistance of the erythrocytes in the veins of the arm. He describes first the technic employed and then reports his personal observations, for which he agglutinated the erythrocytes by means of hypotonic solutions, human bile and antihuman amboceptor. He concludes that the resistance to the bile and to the amboceptor is not sensibly different in the two kinds of blood (capillary and venous), whereas the resistance to the hypotonic solutions is constantly and frankly greater in the capillary blood. He mentions the causes that may determine this greater resistance. He notes the general uniformity of the capillary resistance and points out the practical clinical value of his observations.

Rivista di Patologia e Clin. della Tubercolosi, Bologna

4: 629-724 (Aug. 31) 1930

Immunity Resulting from Cured Tuberculosis. E. Centanni.—p. 700.

Experimental Trials of Vaccination Against Tuberculosis.—Ottolenghi describes the experimental trials of antituberculosis vaccination by the Calmette-Guérin method, as carried out in Bologna in 1926. He states the criteria followed in the evaluation of the effects: direct scrutiny, clinical research and statistical studies. After calling attention to the difficulties encountered in such studies, he surveys the observations collected thus far, which do not, however, permit, as yet, a final judgment, aside from the fact that the vaccine is harmless. The clinical control tests that are now being made will possibly soon permit a fairly accurate appreciation of the value of the method.

Ulcerations of Stomach, Following Tuberculosis of Perigastric Lymph Nodes.—Dagnini's patient, a woman, aged 48, was admitted to the hospital because of pains in the epigastrium—which became worse after meals; diarrhea occurred from time to time; the temperature ranged from 38.3 to 39 C. (101 to 102.2 F.). The state of nutrition was low; the mucosae and the skin were pale. The erythrocyte count was 2,700,000; the hemoglobin was 40; leukocytes, 14,260. On the skin of the supraclavicular regions, many scars covered with crusts, the results of lymph node suppurations, were observed. Enlarged nodes of soft consistency could be felt in the lateral regions of the neck. There were no enlarged lymph nodes in the inguinal or in the axillary regions. The heart was in normal limits. There was a short systolic murmur but easily detectable at all points of auscultation. There was a rhythmic pulse, frequency 98-100. The maximal blood pressure was 108; the minimal, 85 (Pachon). There was a slight decrease in resonance in the apexes of the lungs, more marked at the left. On auscultation—especially at the base—there were moist râles. The abdomen was slightly painful over the epigastrium. No free fluid was noted in the peritoneal cavity. The liver was enlarged. The spleen could not be palpated Slight traces of albumin were found in the urine. The Wassermann reaction was negative. Examination of the contents of a broken-down lymph node was negative as to tubercle bacilli. The patient complained often of a feeling of heaviness in the stomach, even after moderate repasts, with, at times, rather severe pains. During the last three months, the condition became gradually somewhat aggravated. A roentgen examination of the thorax revealed an opacity in the apexes. Near the hilus were roundish dense shadows that appeared to be due to enlarged lymph nodes. In the right axillary cavity, there was a number of enlarged lymph nodes, of pasty consistency. The overlying skin did not present any special changes. Roentgen examination of the cranium revealed at the site of the squamous portion of the occipital bone an erosion of the external table, with the aspect of a small crater. The condition of the patient grew rapidly worse. The lesions in the region of the neck were extensive and deep. From them oozed a quantity of a dense, creamy substance. The patient died four months after admission to the hospital. At necropsy, the stomach was removed and a long incision was made parallel to the greater curvature. In the part above the lesser curvature, near the region of the cardia, four roundish ulcerations were observed. One was located 2 cm. below the cardia; two were a little farther down, on about the same line; the fourth —larger and deeper—was located a few centimeters below the others. These ulcers were of different size and differed as to their depth in the gastric walls. The mucosa in the vicinity of the ulcers was normal in appearance, being of a grayish red. The ulcers were associated with caseous perigastric lymph nodes on the lesser curvature. The question arises: can secondary gastric ulcerations associated with a tuberculous process in the perigastric lymph nodes be regarded as true tuberculous ulcerations of the stomach? In the author's opinion they may be so considered.

Polypous Tuberculous Endaortitis.—Tavernari describes a case of polypous endaortitis of hematic tuberculous origin, which is of interest owing to the rarity of primary tuberculosis of the large blood vessels. The author interprets the unusual manifestation, as regards its relations with other tuberculous lesions found in the organism, as follows: From a primary focus of infection, doubtless either caseous lymph nodes of the hilus of the lung or torpid ulcerations found in the colon, an invasion of bacilli into the circulation took place, which caused changes of a nodular type in the organs attacked (kidneys, liver, pleurae) and, having found their way into the intima of the aorta, caused a specific tuberculous process to develop, which assumed the form of an endaortitis of a polypous character, in which the tubercle bacilli continued to develop.

Ephedrine in Whooping Cough and in Asthmatic Bronchitis.—Agrelo reports good results obtained in the treatment of whooping cough complicated with asthmatic bronchitis by the peroral administration of ephedrine. He gave 0.01 Gm. twice a day to ten children who were taken ill in a home in which they remained during the entire period of the illness. From the first day of the administration of the preparation the attacks of cough diminished to a half and then to a fourth of the number of attacks that the patients had had before the administration of the preparation. However, the discontinuation of the preparation caused a recurrence of the attacks of cough. The author considers the levorotatory alkaloid of the plant *Ephedra vulgaris* as a useful coadjuvant treatment of whooping cough, especially when it is complicated with asthmatic bronchitis or with bronchiectasia or asthma. The action of the alkaloid, though slower than that of epinephrine, lasts longer. Small doses of ephedrine give better results than large doses of epinephrine. The administration of the drug has not been followed by phenomena of intolerance.

Pathogenesis of Gout: Treatment with Mineral Waters. C. Garcia de Cosa.—p. 280.

Examination of Contents of Stomach.—Enriquez de Salamanca used the Ewald-Boas test breakfast, slightly modified to make a determination of the functioning of the stomach. Qualitative and quantitative estimations of the contents of the stomach (sixty minutes after the test breakfast had been ingested) were made in eight normal persons to ascertain the characteristics of the so-called harmony of the gastric digestion, that is, the proper relations between the evacuatory and the secretory functioning of the normal stomach. Tabular reports show the volume of tea, bread and gastric juice in the stomach, as determined by the emptying of the stomach at that time. The contents of the stomach proved to be 35.6 and 45.28 per cent, respectively, of the amount of food ingested. The amount of normal secretion in relation to the volume of tea and of bread remaining in the stomach proved to be of 98 cc. Attention is called to the dissociated evacuation time of tea and bread from the stomach that may be observed. As a rule tea leaves the stomach before bread does, though rarely the opposite may be observed. The author gives a chart in which he represents the evacuation time (including both rates of evacuation from the stomach of bread and tea) as a straight line. The curve of acidity follows the line of evacuation. In normal persons both lines meet sixty minutes after the test meal is given.

Increased Lactic Acid in Blood in Pregnancy: Source.—In a study to determine the source of the increased lactic acid in the blood during pregnancy, Anselmino and Hoffmann found that it was not due either to a disturbance in the functioning of the liver or to a production of lactic acid by the placenta. An investigation of the work metabolism of gravidas, however, showed a great increase in the elimination of lactic acid by the muscles. Shortly after labor the elimination of lactic acid by the muscles decreased and the lactic acid content of the blood returned to normal.

Increased Formation of Lactic Acid in Muscles of Gravidas.—According to Hoffmann and Anselmino, the increased elimination of lactic acid by the muscles in gravidas is caused by a hyperfunctioning of the thyroid during pregnancy. Their observations in this connection are supported by the well known fact that thyroxine increases the formation of tic acid and that the lactic acid contents of the blood in avidas during work and during rest correspond exactly with eir values in persons with exophthalmic goiter.

Prolonged Pregnancy: Induction of Labor.—On the basis of his observations in 857 cases, Köhler believes that in prolonged pregnancy the patient should be kept under close observation with exact control of the relation between the size of the fetus and the size of the maternal pelvis. If because of excessive growth of the fetus a disproportion between the two factors appears, labor should be induced for the protection of the mother and the child even if the normal duration of pregnancy has been exceeded only slightly. This rule should be observed strictly, particularly in old primiparas in whom the rigidity of the soft parts constitutes a grave danger with regard to the life of the fetus and in multiparas who give a history of having repeatedly borne dead or overweight children. Emphasis is laid on the fact that prolonged pregnancy alone does not constitute an indication for induction of labor if the fetus is not overweight.

Effects of Raw Vegetable Diet and of Meat Diet: Self-Experiment.—Willi found a vegetable diet with a high caloric content and a low sodium chloride content that he maintained over a period of ten weeks disagreeable. He was able to keep on a predominatingly meat diet only fourteen days. On the raw vegetable diet his body weight decreased 2,750 Gm., whereas on the meat diet it increased 1,600 Gm. The blood pressure sank during the raw diet from 122:65 to 90:45 mm. of mercury; on the meat diet it did not show marked deviations. Blood examinations during the raw vegetable diet showed a transient hypochromic anemia and a monocytosis of 15 per cent; on the meat diet there were no important hematologic changes. Examination of the acid-base metabolism showed that there was a definite relation between the excretion of organic acids and the hydrogen ion concentration. On the raw vegetable diet the urine became strongly alkaline and there was a great increase in the elimination of organic acids. On both the raw vegetable and the meat diets the chemical composition of the blood remained constant.

Reaction of Vena Cava in Increased Intravenous Pressure.—According to Allen and Page, the increased intravenous pressure that occurs in cases of myocardial insufficiency and emphysema and produces the pathologic manifestations of passive congestion in the viscera does not cause an increase in the thickness of the wall of the vena cava. From this it is to be concluded that the muscular hypertrophy that develops in the veins of the suprarenals in primary hypertension is not caused by the increased intravenous pressure.

Behavior of Gases in Lung.—Anthony states that the simultaneous use of two neutral gases in respiratory experiments is a suitable method for studying the behavior of gases in the lung. By means of this method of study he demonstrated that the gas mixture in the lung is modified by diffusion and he confirmed the observation that the ventilation of the various parts of the lung in healthy persons is not uniform.

B C G Vaccination in Lübeck. M. Kaplan.—p. 1563.

Chlorine Metabolism in Pneumonia: Its Therapeutic Significance.—Scholz points out that in many instances hypertension can be counteracted by reducing the sodium chloride content of the food. This indicates that sodium chloride influences the circulation, and it has been found that its administration effects a stimulation of the vasomotor nerves. In pneumonia, the focus of infection absorbs large quantities of salt, and in the other organs of the body a sodium chloride deficiency develops. It is probable that this lack of sodium chloride is the cause of the vasomotor weakness. In order to stimulate the circulation during pneumonia, it is therefore advisable to supply the organism with sodium chloride. Care should be taken that the diet is not lacking in salt. In addition to this about 10 Gm. of sodium chloride should be given daily. However, because some patients have an aversion to salt it should be administered in the form of sodium chloride injections. The author recommends intravenous injection of 100 Gm. of a 25 per cent solution. In order to avoid tachycardia, the injection should be given slowly. In patients with a weak heart, however, sodium chloride injection is contraindicated. In patients with severe congestion in the pulmonary circulation it is advisable to precede the injection with a venesection. If these precautions are taken complications do not develop, and the stimulation of the circulation, which follows the injection, often has a life saving influence.

Artificial Pregnancy Reaction in Nonpregnant Women: Behavior of Hormone of Anterior Lobe of Hypophysis in Nongravid Organism.—Ehrhardt investigated the behavior of the hypophyseal hormone in the organism of five nonpregnant women who, for therapeutic reasons, had received a blood transfusion from pregnant donors. He found that in the circulating blood the hypophyseal hormone was demonstrable for from two to twenty hours after the transfusion. Analysis of the urine revealed that the hormone was eliminated during the first twenty-four hours. If the hormone is introduced for therapeutic purposes it is therefore advisable not to introduce too large quantities, because they tax the organism and are eliminated in the urine. Small amounts administered at shorter intervals appear to be more practical. The organism of the nongravid woman reacts to the hormone of the anterior lobe of the hypophysis in practically the same manner as the pregnant organism, that is, if the blood stream contains a large amount of the hormone it is eliminated with the urine, and a positive pregnancy reaction can be produced.

Case of Gunshot Injury of Brain. A. Isserlin.—p. 305.

Enlargement of Sternal End of Clavicle as Sign of Congenital Syphilis.—Higoumenakis calls attention to a sign of congenital syphilis which, he says, he had first described. The sign, which consists in enlargement of the sternal end of the clavicle, was frequently found among the 1,500 patients examined. The most characteristic twenty-three cases are reported. In all instances, besides this sign, other signs of congenital syphilis were present; in seven instances, the Wassermann reaction was positive. The sign was never observed in healthy persons or in patients with an acquired syphilis. Roentgenograms indicated that there was not an abnormal attitude of the patient or a distended bursa of the sternoclavicular joint, but an exostosis of the internal end of the clavicle. The development of the exostosis is explained by anatomic, biologic and mechanical factors. It is known that the sternal end of the clavicle first consists of connective tissue which is early transformed into bone tissue. The syphilitic spirochetes carried by the blood become as readily localized in the connective tissue as in the lymphatic spaces and in the organs of the fetus. Later, as the result of the frequent movements of the arm and of the consecutive friction of the clavicle against the sternum, an activation of the spirochetes occurs. Their toxins cause an irritation resulting in the appearance of a chronic periostitis and of an exostosis in the sternal end of the clavicle. In thirteen cases in which the patients were left handed, the enlargement was situated on the left clavicle.

Anemia in Premature Infants.—Silberschmidt states that, in well fed premature infants with anemia during the first three months of life, reduced iron is not of value. In nine premature infants in whom he used this form of treatment it increased neither the hemoglobin content of the blood nor the number of erythrocytes. The anemia of premature infants is apparently not caused by an iron deficiency and therefore iron that is administered therapeutically is not utilized.

Effect of Diet of Milk on Guinea-Pig Nurslings.—In a series of experiments on guinea-pig nurslings, Bilek was unable to confirm Sudbolt's observation that when new-born animals are placed on an exclusive cow's milk or goat's milk diet they develop scurvy and anemia. Not only did the animals fail to develop scurvy and anemia but their rate of growth was the same as that of the rest of the litter, which were suckled by the mother.

Desensitization Therapy in Bronchial Asthma.—Petow and Wittkower used cutaneous tests and desensitization treatment in 116 patients with bronchial asthma. A tabular report indicates that thirty-six recovered completely, thirty-four were considerably improved, twenty-one showed temporary improvement and twenty-five were not influenced. It was noted that the older the patient was and the longer the asthma had existed the poorer were the chances for recovery. Regarding the cutaneous tests, it is stated that they have been overvalued. Because nonspecific desensitization frequently brings satisfactory results, the practitioner may omit the complicated cutaneous tests. In cases that are refractory to treatment, cutaneous tests should be performed in special institutes. If the specific allergen is known, it is advisable to remove it from the surroundings of the patient. This is the most effective treatment. In cases of hypersensitivity to dust, specific desensitization with dust extract has proved effective. If the specific allergen is not known, nonspecific desensitization with tuberculin or peptone gives favorable results in about 60 per cent of the cases.

Production of Osteitis Fibrosa by Means of Parathyroid Extract.—Jaffe et al. reasoned that if extirpation of a tumor of the parathyroids has a therapeutic effect on an existing osteitis fibrosa, it should be possible to produce changes in the bones by injection of parathyroid extract. Experiments were made on guinea-pigs and on dogs. In guinea-pigs it was observed that, following subcutaneous injection of parathyroid extract, such changes developed in the bones, on which the diagnosis of osteitis fibrosa is usually based, namely: (1) bone resorption and development of Howship's lacuna with numerous osteoclasts, (2) fibrous substitution of the bone marrow, (3) formation of osteoid tissue, and (4) hemorrhages. In dogs it is more difficult to produce changes in the bones, because doses that are large enough to effect the changes frequently cause death. Nevertheless by gradually increasing the doses the typical characteristics of osteitis fibrosa could be produced. During the experiments the animals were on a normal diet. The changes in the bones therefore are caused neither by vitamin deficiency nor by nutritional disorders but must be the result of the injections of parathyroid extracts.

Relation Between Stomach and Kidney.—In a patient with carcinomatous occlusion of both ureters, Steinitz observed a complete anuria lasting twenty-four days. Continuous blood tests revealed that the rest nitrogen, indican, potassium and the phosphates were increased, while the chloride showed a considerable decrease. The calcium and alkali reserves became subnormal only shortly before death. Frequent vomitings were noted as the main symptom. Examination of the gastric juice, obtained following histamine injection, and of the vomit revealed a considerable amount of nitrogen. It may be assumed that the elimination of the poisonous products of metabolism by way of the stomach enabled the organism to tolerate the anuric condition for a long time, without more severe disturbances.

Methods of Invisible Writing.—Langen describes various kinds of fluids with which invisible writing may be produced and also how they can be made legible. Such invisible writings are frequently used by criminals confined in prisons, and a knowledge of the various methods and how to decipher them is of greatest significance for the criminologist. The author first mentions various chemicals with which invisible writings may be produced. A small amount of nitric acid is added to hydrochloric acid and copper is dissolved in this mixture; then water is added. Writing produced with this solution disappears when dry and becomes visible again when made moist. This is also the case in the so-called Widemann's ink, which consists of 1 part of linseed oil in a dilute ammonia solution. Other fluids with which invisible writing may be produced are milk, sugared water, juices of apples, lemons or oranges, also acacia solution. Writings produced with these substances can be made visible by a slight moistening such as is produced by breathing or by sprinkling them with dust or with ashes. If diluted ink is poured over the paper the writing will also become visible. Writings produced with coffee, tea, or water that has been used for washing, can be made visible by applying heat with a hot flatiron. The author points out that in these methods of writing the glaze of the paper is either destroyed or heightened and that this can be noted when the paper is scrutinized at an oblique angle. Writings that do not affect the glaze of the paper can be produced with saliva or with blood that has been strongly diluted with either saliva or water. Writing produced with diluted blood becomes visible when an alcoholic eosin solution is applied. Saliva writing can be made visible by applying first moisture and then ashes or dust.

Dreams of Patients with Pulmonary Tuberculosis.—Hoke asserts that the progressive destruction effected by the tubercle bacillus affects not only the body of the patient but also the psyche, and if the psyche is affected it is understandable that the dreams, which according to psychoanalysis are the psychic manifestation during sleep, have certain peculiarities. The author inquired into the dreams of about 100 patients with severe tuberculosis. The number of men and women was about equal. The ages of the patients ranged between 20 and 42 years. Dreams of children and persons during the age of puberty were not considered. The author found that patients with severe tuberculosis dream much, that women dream more than men, and that the dreams of educated people are surprisingly similar to those of simple workers. The dreams of tuberculous persons usually indicate fear and anxiety, and not far past but present experiences are their main subject. Wish dreams, sexual dreams and symbolic dreams are rare.

Relation Between Acute Rheumatic Arthritis and Tuberculosis.—Reitter and Löwenstein point out that the forms of acute arthritis designated as rheumatic are known in their clinical manifestations; however, their etiology is as yet not entirely clear. In previous investigations on fifteen patients with acute or subacute polyarthritis, Reitter detected rod-shaped bodies, with the typical arrangement of tubercle bacilli, in the exudates of the joints. After that both authors employed Löwenstein's culture method to detect tubercle bacilli in the blood of patients with acute rheumatic polyarthritis, thinking that during the fever period, especially in the beginning stage of the disease, tubercle bacilli should be demonstrable. This assumption has proved correct. Nine case reports of patients with acute rheumatic polyarthritis show that it is not necessary that the patients show the usual symptoms of tuberculosis, and that nevertheless tubercle bacilli are present. The authors think that the presence of the tubercle bacilli in these patients is not a mere concurrence but that a causal relation exists between tuberculosis and the acute rheumatic polyarthritis. However, further investigations will be necessary to determine the exact nature of the relation.

Sulphur Therapy in Furunculosis.—In the sulphur therapy for furunculosis described by Herxheimer et al. the patients are placed in chambers into which, by means of compressed air, water containing sulphur is sprayed. The water employed for this treatment is obtained from natural sulphur springs, and beside sulphur it contains numerous other minerals. The authors found that the therapeutic results of this treatment were favorable in most cases. New furuncles did not develop and the existing ones healed rapidly.

Cure of Ulcers of Leg by Obliteration of Varicose Veins.—Isaak asserts that varicose ulcers of the leg are most successfully treated by obliteration of the varicose veins. This he attains by injecting 10 cc. of a hypertonic sugar solution. In order to insure good results it is essential that the section of the vein to be obliterated is as bloodless as possible. This is readily effected by the usual procedures resorted to, such as elevation of the leg, and forcing the blood backward. The author employed this technic in more than 100 cases. He gives detailed reports of nine cases. Not all varicose ulcers yield equally well to this treatment. According to the etiology, the healing tendencies differ considerably. The crater-like ulcerations that are surrounded by a thickened and inflamed skin, and are the result of thrombophlebitis, heal slowly; likewise, the flat ulcers, surrounded by eczematous, erythematous, hypertrophic or hypotrophic skin, heal comparatively slowly. However, the frequently deep and extensive ulcers that are caused by embolic occlusion of the veins, but which are usually surrounded by healthy skin, heal rapidly. Refractory to treatment are those ulcerations that have existed for several decades and that encircle large parts of the leg. The complications of the varicose syndrome, such as the eczema and the ulcer itself, necessitate of course, besides the obliteration of the varicose veins, also local therapeutic measures. The author describes bandages and their application. In the conclusion he points out that ulcerations and eczema may in many instances be prevented by early treatment of varicose veins. As a special advantage of his therapeutic method he considers the fact that most patients can be cured by ambulatory treatment. If contraindications are strictly observed, the treatment is without danger and the results are permanent. Relapses may be avoided by early treatment of newly developing varicose veins.

Irradiated Milk for Nursing Mothers for Prophylaxis of Rickets.—Scheer and Sandels point out that fresh milk, which is intensively irradiated under exclusion of oxygen, in an atmosphere of carbon dioxide, acquires antirachitic properties and the taste and odor remain unchanged. It was found that when from 400 to 500 cc. of such milk was given daily to children with severe rickets, they recovered in from four to eight weeks. An added advantage was that the milk was harmless. Up to now this method of treatment or prophylaxis of rickets was not available for breast-fed infants. Therefore the authors investigated whether the antirachitic factor of irradiated milk could not be transmitted to the child by giving the mother irradiated milk. Premature infants, in whom the early symptom of rickets, craniotabes, is most noticeable, were fed with milk from wetnurses, who drank daily 500 cc. of irradiated cow's milk. The milk of these women was also given to several rachitic rats. Both experiments proved that human milk acquires antirachitic properties if the mother drinks irradiated milk.

Acid-Base Equilibrium in Diseases of Heart and Kidneys.—Lipets and Pismarev studied the acid-base equilibrium in fifty-four patients with various diseases of the heart and of the kidneys, in whom the alkali reserve, the alveolar carbon dioxide tension, the blood urea and the chlorides in the urine were repeatedly determined and in whom a functional renal test was made. A decrease in the alkali reserve and a parallel decrease in the alveolar carbon dioxide tension were observed during the decompensation period in both heart and kidney diseases, usually more pronounced in the kidney diseases and in direct proportion to the aggravation of the condition of the patients. As a rule a simultaneous decrease in the carbon dioxide in the expired air, expressed by dyspnea, was noted. In the presence of some complications in the lungs (stasis, bronchitis, emphysema, asthma), a dissociation between the condition of the patient and the changes in the alkali reserve and in the alveolar carbon dioxide tension was observed. In nephrosis and in localized glomerulonephritis a decrease in the alkali reserve and in the alveolar carbon dioxide tension was not observed. A change was not found in the chloride content of the urine. The blood urea was increased in almost all patients with diseases of the kidneys, but in only a few patients with diseases of the heart. Usually in these last cases there were some complications in the kidneys, and even then the blood urea did not rise above 56 mg. Hypocapnea always preceded the increase in the blood urea, and the decrease in the blood urea in the course of the disease did not indicate an improvement in the condition of the patient unless it was accompanied by an increase in the alkali reserve and in the alveolar carbon dioxide tension.

Effect of Roentgen Rays on Permeability of Normal Cells and of Cancer Cells.—The experiments of Magat concerning the effect of roentgen rays on the excretion of phosphates by the living tissues in vitro revealed a considerable difference between the reactions of normal tissue and of cancer tissue. Specimens of normal liver and of Jensen's sarcoma and carcinoma, secured from living rats and mice, were placed in Ringer's solution, kept at 37.5 C. or at room temperature, and the evaluation of the amount of phosphates that had diffused into the Ringer's solution from the tissues was made before the exposure of the specimen to roentgen rays and twenty minutes after the exposure. After the exposure, the excretion of phosphates was observed to increase considerably in the experiments with the specimens of normal liver, whereas no change or even a decrease in the excretion of phosphates was observed in the experiments with the specimens of tumor. On the basis of the results obtained in the other series of experiments made on the same specimens and concerning the effect of sodium cyanide on the excretion of phosphates before and after the exposure of the specimens to roentgen rays, and also on the basis of the effect of the roentgen rays on the acid imbibition in the normal tissue and in the cancer tissue (in the previous experiments of the author) and on the electrical resistance of the normal cells and of the cancer cells (in the experiments of Wassermann), the author explains the results of the experiment by the specific changes in the surface permeability of the cancer cells.

Carcinoma of Ileocecal Valve in Girl Aged Fifteen.—Pojarisky reports a case of carcinoma in the region of the ileocecal valve in a girl, aged 15. The acute onset, the short duration of the disease and the age of the girl made the case interesting, though the occurrence of carcinoma at the age of 15 years is not exceptional; thus, Radko in his statistics reported 145 cases of carcinoma in children aged from 1 to 15 years and forty-nine more cases in young persons aged from 15 to 20 years. The first symptoms of the disease in the case reported (pain in the right iliac region, vomiting and headache) were observed in the previously always healthy girl, at the end of April, 1929, passed quickly and reappeared twice in May. In June she was sent to the hospital with the diagnosis of acute appendicitis. But at the operation a tumor of the cecum was found, and an entero-anastomosis was performed. She died at the end of July, about three months after the appearance of the first symptoms. At the necropsy and the subsequent microscopic examination of the specimens a colloidal carcinoma of the cecum was diagnosed. The maximum of the cancerous infiltration invading the whole cecum was in the region of the ileocecal valve, the opening of which hardly admitted a little finger. Numerous metastases were found in the regional ileocecal and retroperitoneal lymph nodes, notwithstanding the short duration of the disease.

CLINICAL SIGNS OF HEART DISEASE

WITH PARTICULAR REFERENCE TO ETIOLOGY *

JAMES B. HERRICK, M.D.
CHICAGO

My special purpose in this paper is to stress the importance of a consideration of etiology in the diagnosis of heart disease. Perhaps most of us admit that an etiologic diagnosis is important. Why, then, take time to discuss the question? The answer is that in practice the etiologic feature is largely overlooked.

The classification of heart disease has been, and still is, in a crude state. Chaotic is too strong a word to use regarding it, but it is decidedly unsystematic and unsatisfactory. The same is true of nomenclature. No wonder, then, that there is little uniformity in the diagnoses made by even the best physicians. The condition diagnosed aortic regurgitation by one is called by another syphilis of the aorta and aortic valves; by a third, aortic leak with cardiac hypertrophy but good compensation. The next patient is said by one physician to have mitral stenosis. The disease is labeled auricular fibrillation by a second, heart failure by a third, rheumatic valvular disease by a fourth. One physician stresses the anatomic location of the lesion and its pathologic nature, another the disturbance of function, another some striking clinical phenomenon, a few the etiologic factor.

Why should not physicians employ in diagnosis the classification suggested by the Heart Committee of the New York Tuberculosis and Health Association, which is in conformity with the nomenclature for cardiac diagnosis approved by the American Heart Association? The case of aortic leak might then be called syphilitic aortitis with aortic regurgitation, cardiac hypertrophy, regular sinus rhythm, class 2 A; i. e., activity slightly limited. Here the etiologic and pathologic anatomic features are plainly set forth with the clinical and functional facts also considered. The case of mitral stenosis may be described as rheumatic mitral disease with stenosis, auricular fibrillation with activity seriously limited, classed briefly as class 2 B. Again, etiology, anatomic pathologic lesion and functional capacity are expressed. All of these features may with advantage be included in the diagnosis.

But some physicians may say, "Why all this fuss about these details of diagnosis?" What a practitioner desires to know is, first, whether or not there is organic heart disease or only a cardiac disturbance due to conditions outside the heart, and, second, whether the heart is competent to perform its work. He wishes to tell his patient how he may live so as to maintain for as long a time as possible a fairly efficient heart. The attitude of these physicians is the same as that of the medical student who in ward class, after the subject of the differentiation of the various valvular lesions had been gone over and had been studied in several patients, asked me the embarrassing question, "But, Professor, what difference does it make? And this question must often occur to us as we see the dyspneic, cyanotic and edematous patients with irregular and laboring hearts. What difference does it make whether the valve involved is the mitral or the aortic, whether the myocardium is fibrotic from preceding inflammation or from a degenerative process, whether the hypertrophy is due to a primary valvular or renal cause or is part of an essential hypertension? The fact that confronts the physician is that here is a patient with an incompetent heart, in urgent need of help. Without consideration of the finer points of diagnosis, anatomic or etiologic, he must proceed immediately to measures of relief which will be practically the same, no matter what the cause. So he advises rest, proper diet, elimination, digitalis or morphine as seems appropriate.

Now, this is not really a fair view of the situation; at least it is a narrow view. Of course, the patient's welfare is the prime consideration. He is in immediate danger and must be given first aid without too much discussion of the academic question as to how and why he came by the distressing condition. But it is important that the physician should know causes. The outlook for the future and the subsequent treatment may depend much on such knowledge. A heart muscle incompetent from a suddenly developing infarct due to an acute coronary thrombosis may have an entirely different prognosis and demand a different treatment from the myocardium that has been slowly but progressively failing from the development in it of patches of fibrosis due to gradual occlusion of many coronary twigs. An aorta and aortic valve deformed from a still active syphilis imply an outlook and therapy different from that demanded by the lesions of old-age atheromatosis.

Let me interject another comment. It is sometimes felt by the practitioner that the physican who is meticulous as to diagnosis and classification based on an accurate knowledge of causes and the details of the pathologic and physiologic processes involved is an unpractical man, particularly if he is a physician whose training has been largely in the hospital and laboratory. This is surely wrong. There is no inherent incompatibility between scientific habits of thinking and practical common sense. In fact, some of the most scientifically minded practitioners are the most sound in their practice. Other things being equal. the scientifically trained mind will think more clearly and logically, will direct practical activities more rationally than the so-called

---

* Read before the Section on Practice of Medicine at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

empiric mind that is bolstered up chiefly by "experience." It is sometimes assumed that empiricism and practical common sense are synonymous. This is by no means always true. Empiricism has no monopoly on common sense. The empiric physician is all too frequently most gullible as to acceptance of fantastic theories, most unthinking or even dangerous in his therapy. In the final analysis, a good deal depends on what kind of a mind and how much of a mind the physician, whether scientific or practical, had to begin with.

In a discussion of clinical signs of heart disease with particular reference to etiology, the questions involved are difficult, the answers somewhat uncertain. Too many cases are encountered in which even with greatest care the cause of the cardiac symptoms may escape detection. But it is only by trial and search that knowledge will come. The search for causes, the comparison of results, together with statistical, clinical and necropsy studies will enable one to be more accurate in the diagnosis than has been the case in the past. To be impressed by the lack of uniformity in diagnosis, one has only to go to the health department of any large city and look over the causes of death as recorded on the death certificates. Syphilis as a cause is rarely put down, largely because of the physician's desire to shield the reputation of the dead man and his family. Pericarditis, endocarditis and myocarditis and angina pectoris are in evidence. But—I am citing Dr. Halsey as authority for the statement—other forms of heart disease, largely the senescent and arteriosclerotic group, make up 88 per cent of cases. On the whole, the diagnoses are vague and lack uniformity. For purposes of study and comparison, they are of little value. But they should be of great value. A statement on the death certificate as to the cause of the disease, or even that the cause was unknown, would be helpful. It would show to the student of statistics that this point had been considered and would permit of deductions that would otherwise be unwarranted.

Only a few suggestions will be here offered. As to how to diagnose etiologically: My purpose is rather to show the necessity and advantage of such a diagnosis. No claim is made as to completeness in the presentation. To go over the entire subject would involve a repetition of the old story of the importance of studying the patient by the familiar methods of history taking, physical examination and repeated observation, with, when necessary, aid from laboratories as of chemistry and bacteriology, from instruments of precision such as the electrocardiograph and x-ray machine, and from specialists. In general, more facts as to etiology will be elicited by the history and physical examination and repeated observation, all of which implies closer personal contact between physician and patient, than by the laboratory and instrumental tests.

The age at which symptoms were noted may give the clue to congenital heart disease. The partiality of rheumatic disease for early years, of sclerotic and degenerative disease for the later years, and of syphilitic cardiovascular disease for the middle period of life is to be remembered. In connection with rheumatism, careful inquiry may elicit a history of mild chorea or suggestive growing pains. Inquiry should be made as to previous purpura or tonsillitis. Syphilis may be betrayed by painstaking search for suspicious facts in the history such as the supposedly innocent sore, alopecia, the stubborn sore throat. Or the obscure precordial distress some years ago with a little fever, the physician puzzled to account for a slightly rapid pulse, and a soft murmur at the base may tend to show that syphilis is the probable cause of the aortic lesion. And, of course, the physical examination for stigmas of this disease in all organs should not be forgotten. In other words, the diagnosis of syphilis of the aorta, valves, coronary artery or myocardium is not to depend on the Wassermann test or the roentgenographic observations alone.

So with acute endocarditis. Bacteriology should, of course, be employed. But the clinical features of rheumatic endocarditis, of the subacute type due to *Streptococcus viridans* or the forms due to pyogenic germs like the staphylococcus are in general so distinct and clear cut as to permit of diagnosis in spite of negative bacteriologic reports.

Then there are the thyroid gland cases. Here again the history and the examination are of fundamental importance. The estimation of the basal metabolic rate is often a deciding factor in reaching a conclusion. Good judgment, however, is necessary in interpreting the results of this test. Slight variations from the normal should not be given too great weight unless checked by tests repeated under carefully controlled conditions. On the other hand, it should not be forgotten that hearts that are large, the seat of murmurs and wildly irregular may have as an aggravating or even an essential cause of the serious disturbance a long perverted overactivity of the thyroid gland.

Other toxic causes may occasionally be recognized—too much tea or coffee. Extrasystoles from tobacco are seen. Digitalis, cocaine and other drugs may give rise to irregularities of rhythm. Some infectious diseases, as diphtheria or scarlet fever, may be associated with arrhythmia which, while primarily bacterial in origin, is really due to the local effect of toxins. The cardiac upsets associated with uremia should be kept in mind. And gastro-intestinal disturbances are at times responsible for the cardiac symptoms that bring the patient to the physician.

There is a group, and it is not a small one, that is commonly called the cardiac neuroses. No organic disease of the heart can be made out; there is no detectable bacterial or toxic factor, no disease in other organs—lung, kidney, thyroid, stomach, bowel—to explain it. Yet the patients are real sufferers, the heart is irritable with a rate tending to be rapid, there are palpitation, precordial distress, breathlessness, fatigue, sweating, flushing of the skin. Cases with the long category of symptoms included under the term neurocirculatory asthenia or effort syndrome show mental variations all the way from slight degrees of apprehension to the extreme types of fear that lead one at times to question whether a phobia has not gotten over into the group of the pathologic psychoses that border on insanity. The search for the cause here is not to be limited to a hunt for evidence of anatomic change in the heart, to increase in size, altered blood pressure, abnormal electrocardiogram, detection of a microbic or toxic agent. These things, of course, should be searched for. Obscure toxic or endocrine disturbances may thus be uncovered. But in these cases there is a chance for the wise physician to put to practice all that he knows about the human mind. He may not be versed in the various schools of psychology, may not know whether he is searching for a cause according to the tenets of William James or Bergson or Freud, but he must go into questions of heredity, of childhood training, of home and social surroundings. Love affairs, skeletons in closets, financial status, day dreams and night dreams, ambitions and failures—all these must be considered.

A concrete case has come to my attention as I am writing this paper. A woman of forty-eight was troubled with fatigue, rapid pulse, a small goiter, a slightly elevated blood pressure, sleeplessness. Certainly there bulked very large in the etiology the fact that she was an introspective nurse, that she had had financial reverses and that she was annoyed by three well meaning but nagging friends, who insisted that the nurse come to live with them, give up her own doctor and change to one of their choosing. She declared frankly to me, as she had to her physician, that she simply could not live happily under the same roof with either one of her two sisters. They got on her nerves. As to living with her friend and former partner, that seemed out of the question because this friend had just married the patient's sweetheart, whom she herself had fondly hoped to marry and whom she still violently loved. Some hypertension, some overwork during a recent influenzal attack, possibly some thyroid influence were causative factors in her condition, but surely a large psychic element was present. The patient frankly said her symptoms, she believed, were chiefly emotional.

This case further illustrates an important feature of diagnosis from a causal point of view. There is often more than one cause. We must determine as nearly as possible what are underlying causes—heredity, so-called constitution, general arteriosclerosis, poor hygienic surroundings—and what is the immediate cause of the present cardiac upset. Proper management often depends on a knowledge of the multiplicity of causes with an appreciation of the relative importance of each. A very important group is the one in which the heart disease depends on some general systemic disease—arteriosclerosis, hypertension or such diseases as nephritis, diabetes or gout.

Lastly, in some cases the exact cause for the cardiac condition cannot be discovered. Etiology is for the time at least unknown. But this fact, as has already been said, should be noted in the diagnosis.

I have consciously strayed a little from the title of this paper. I have done this because it seemed possible in limited space to touch on only a few suggestive facts as to methods of diagnosis from the etiologic standpoint. Also, it seemed quite as important to stress the need for, and the advantage of, such a form of diagnosis. If some system of classification and nomenclature, such as that of the Heart Committee of the New York Tuberculosis and Health Association and the American Heart Association, is followed, it will make for uniformity, clarity and scientific accuracy. We shall thereby become better practitioners and the patient will be the gainer.

122 South Michigan Avenue.

Lean Types of Dyspituitarism.—In all that has been written about fat metabolism in relation to the hypophysis and hypothalamus, emphasis has been laid almost exclusively on adiposity and little said of emaciation. If the adiposity is a paralytic phenomenon, as some assume polyuria to be, should we not expect to see a significant loss of weight as an irritative phenomenon? The condition of adiposogenital dystrophy has so long engaged the attention of clinicians, the fact that there are lean as well as fat types of dyspituitarism associated with hypophysial as well as with hypothalamic tumors, has not received the attention it deserves.—Cushing, Harvey: Neurohypophysial Mechanisms from a Clinical Standpoint, Lister Memorial Lecture, *Lancet*, July 26, 1930.

THE PROGRESSIVE NATURE OF CARDIAC FAILURE*

C. SIDNEY BURWELL, M.D.
NASHVILLE, TENN.

> It is of use from time to time to take stock, so to speak, of our knowledge of a particular disease, to see exactly where we stand with regard to it, to inquire to what conclusions the accumulated facts seem to point, and to ascertain in what direction we may look for fruitful investigation in the future.
>
> —*Osler.*[1]

Heart disease is the most frequent cause of death in the United States today. It causes not only many premature deaths but also a great amount of crippling or disabling illness. The control of heart disease is thus a problem the solution of which is of first importance to the public health.

It is obvious that the most successful method of preventing or postponing death from heart disease is to prevent the occurrence, to reduce the severity or to shorten the duration of the conditions leading to heart disease. Speaking in general terms, this means the control of hypertension and vascular diseases of acute rheumatic fever, and of syphilis. The most effective way, then, to attack heart disease is to attack syphilis, hypertension and acute rheumatic fever. This, however, is more easily said than done.

Essential hypertension, for example, is often recognized as such in the early years of the disease and is an abnormality frequently encountered in making periodic physical examinations. A great deal is known about its effects but little about its cause. Indeed, the knowledge of its cause is so limited that it may be compared to the knowledge of the cause of diabetes before the demonstration of its basis in pancreatic dysfunction. With this limitation of knowledge, even when hypertension is recognized early little can be done about controlling it and practically nothing about curing it. It causes such a considerable proportion of heart disease that when an understanding of hypertension has been achieved and translated into effectual preventive measures a most important step in the control of heart disease will have been taken.

The situation in regard to acute rheumatic fever is slightly more encouraging. The problem is under attack from many sides and it may be hoped with some optimism that soon there will be satisfactory means of prevention and cure. The means now used are partially effective in prolonging the duration and improving the quality of life, but they certainly do not constitute a solution of the problem. Prevention of individual cases of rheumatic heart disease is of more value to the individual than prevention of most other types because the relative youth of the patients means the saving of more years of life.

Against syphilis much more potent weapons are available and there is reason to believe that the early, prolonged and intelligent treatment of syphilis by the means at hand would result in a fall in the incidence of syphilitic heart disease. This fall will be brought about, not by people interested primarily in heart disease but by those who are treating early syphilis well.

Recognition of limitations in controlling these conditions makes it clear that in the present state of medical knowledge it is not possible to make an effective attack on heart disease as a whole by preventing its causes. It is, then, urgently necessary to encourage investigation into the problems of its causes: hypertension, acute rheumatic fever and syphilis. Meanwhile physicians must do what they can by the application of what is known about them now.

---

[1] Osler, William: Malignant Endocarditis, Lancet 1:415, 1885.

Once heart disease due to these or other causes is established, the rate of its advance may be retarded by wise care. With the best care in the world, however, heart disease of these types will in the long run usually eventuate in heart failure. It is, of course, heart failure which actually results in the death of the patient. This being so, the second method of attack on the problem of heart disease must be the postponement or successful treatment of heart failure.

By heart failure is meant a group of symptoms and signs dependent on congestion in various parts of the body. These symptoms and signs usually include dyspnea (which may be continuous or of the paroxysmal type), engorgement of the neck veins, distention of the liver, peripheral edema and pulmonary edema, and often collections of fluid in the serous cavities. From this discussion are excluded the cases of acute circulatory failure such as are seen in infectious diseases or after hemorrhage. This is a different thing and based on different mechanisms.

The development of the picture of congestive heart failure carries with it an extremely grave prognosis. Complete recovery from the condition is practically unknown and response to treatment, while often striking, is only temporary.

The average duration of life after the onset of the symptoms of congestive cardiac failure is unpleasantly brief. According to Romberg,[2] who studied a large group of poor people with heart failure, the duration of life after the onset of severe symptoms was six months. I have recently analyzed the histories of twenty-five patients who died of heart failure in the Vanderbilt University Hospital and who came to autopsy. The limitation of the study to those patients subjected to postmortem examination made it possible to eliminate cases in which conditions outside the heart were important factors in the patient's death. The average duration of life in these patients after the onset of definite failure was seventeen months. This term is much less than the average duration even of certain incurable and malignant conditions, such as malignant lymphoma. It is, of course, often possible to adjust the patient's life to his disease so that he may survive with reasonable comfort for years, but even under the best conditions when a patient has once developed the classic evidences of what is called heart failure he is sentenced to death and the fatal event is seldom long postponed. Even when the fatal event is postponed, the change usually represents a commutation of sentence to life imprisonment rather than a pardon.

It is important to decide the point as to whether this is necessarily the case. Does heart failure represent an irreversible end stage, is it a road that leads inevitably and quickly to the gate of death, or is it the result of changes which physicians may learn to control and to reverse?

At the outset, it may be admitted that, in spite of the gloomy average, there are people with heart failure who survive for some years. In this series of twenty-five cases, the extremes of duration were three weeks and seven years, and many of the patients had months of comfortable activity after a classic first attack of heart failure. This would indicate that there are at least some stages in which the processes (whatever they are) are reversible and this observation lends the possibility of success to the search for a controllable abnormality as the basis of failure of the heart.

It is first necessary to say a word about the possibility that heart failure is due to lesions or functional disturbances outside the heart itself; in the nervous system, for example, or in the peripheral circulation. It is not to be doubted that an initial attack of heart failure produces changes in the body apart from the heart itself and that some of these changes favor the continuation or recurrence of the manifestations of failure. This is another way of saying that heart failure is the first step of a vicious cycle which, once established, tends to progress. Harrison and Pilcher,[3] for example, have shown that edema not only increases the work of the heart, certainly a bad thing for a failing organ, but leads to a loss of buffers from the body muscles and thus reduces the factors that tend to protect the heart from overwork. Their work on edema has been confirmed by the researches of Barker and Kirk.[4] Eppinger, Kisch and Schwarz[5] have observed changes which they believe indicate a difficulty in the resynthesis of lactic acid in the general musculature. This type of change is certainly important but must, in the beginning, be secondary to a primary fault in the heart itself. It is the nature of that primary fault in the heart with which we are now concerned.

It is true that most cases of congestive heart failure follow long-standing cardiac overwork, particularly overwork in the form of valvular disease or hypertension. Neither the severity nor the duration of the overwork, however, coincides with the severity or with the time of onset of failure, so that it is necessary to seek a factor or factors beside the overload itself. Some factors that accelerate the progression of heart failure are those that increase the load: anemia, chronic pulmonary disease, pregnancy; in other cases failure may progress in spite of an actual diminution of the hypertension originally responsible for it and in spite of a life carried on at a low level of activity.

For about a century, beginning with Laënnec, emphasis has been placed on abnormality of the cardiac muscle as an important immediate cause of heart failure. A great clinician, William Stokes[6] of Dublin, observed in 1854, "It will be seen that, while the diagnosis of valvular disease depends upon the existence and appreciation of certain physical signs, the questions of prognosis and treatment depend upon the condition of the muscular portions of the heart." If it be granted, for the sake of our analysis, that cardiac failure depends on a myocardial abnormality, then the next question is the nature of the myocardial defect. The answer to this question should determine both the possibility and the method of treating the myocardial defect. There is no lack of suggestions regarding the nature of the abnormality in the muscle. Three familiar hypotheses are as follows:

---

[3] Harrison, T. R., and Pilcher, Cobb: Studies in Congestive Heart Failure: I. The Effect of Edema on Oxygen Utilization, *J. Clin. Investigation* 8:259 (Feb.) 1930; II. The Respiratory Exchange During and After Exercise, ibid., April, p. 291.

[4] Barker, M. H., and Kirk, E. J.: Experimental Edema (*Nephrosis*) in Dogs in Relation to Edema of Renal Origin in Patients, Arch. Int. Med. **45**:319 (March) 1930.

[5] Eppinger, Hans; Kisch, Franz; and Schwarz, Heinrich: *Das Versagen des Kreislaufes*, Berlin, 1927.

[6] Stokes, William: *Diseases of the Heart and Aorta*, Philadelphia, 1854.

1. The basis of heart failure is an actual destructive lesion of myocardial tissue, either grossly or microscopically recognizable.
2. The basis of failure is an interference with the blood supply by obstructive lesions of the vessels of the coronary circulation.
3. Lesions of the specialized conduction tissues may lead to abnormal function and so to failure.

While it is clear that all these types of lesions may play a part, and occasionally (usually in old people) an important one, in the development of heart failure, it is equally clear that no one of them nor any combination of them accounts for a large proportion of the cases coming to autopsy. The classic observations of Aschoff and Tawara[7] and the recent book by Cabot[8] emphasize the fact that in most cases failure of the heart is not to be explained on the basis of anatomically demonstrable lesions in the muscle. It is fortunate that this is so, for such anatomically demonstrable lesions are almost of necessity permanent and often, indeed, progressive. If such lesions are the only basis of failure, the problem of its treatment is probably quite insoluble. But if one agrees that the myocardium is at fault and yet can assign no structural abnormality as the basis of its failure, one may turn the attention to functional changes. Here there is more ground for hope because functional changes are often reversible. What functional alteration in the muscle is to be blamed is not known. Certain reversible changes are known, however, which are definitely associated with some cases of heart failure.

It has been observed for some years by Zondek[9] and by Fahr[10] that certain cases of heart failure are associated with myxedema and are relieved of the cardiac symptoms by the administration of thyroid substance. An even better example is to be found in the cases of heart failure observed in association with beriberi by Scott and Herrmann,[11] by Aalsmeer and Wenckebach,[12] and by Keefer.[13] In these patients the manifestations of heart failure disappeared after the administration of vitamin B. These conditions illustrate a myocardial functional change severe enough to be responsible for heart failure and yet reversible by simple treatment. The hope that animates many workers now is that some functional change like these will prove to be an important factor in the heart failure associated with valvular disease and with hypertension. Work is in progress in many laboratories and clinics directed toward a solution of this problem. In Vienna, Kutschera-Aichbergen[14] has observed a fall in calcium and a diminution in lipoids in the heart muscle of patients dead of failure. In Nashville, Harrison, Calhoun and Pilcher[15] have demonstrated in such cases a diminution of the potassium content of the heart and have brought experimental evidence which relates this fall to fatigue of the muscle. The invariable association of cardiac hypertrophy with failure has been commented on by Christian.[16] It has been suggested that failure may have to do with difficulty of diffusion through enlarged muscle fibers. Such studies as these promise increased understanding of and therefore increased ability to control the changes in the heart muscle which lead to the development of heart failure.

Heart failure usually occurs in successive attacks which come closer and closer together and respond less and less to digitalis and other therapeutic means. The functional changes in the heart muscle may well become irreversible as the condition progresses, but there is reasonable ground for hope that in the early days or weeks of failure they are reversible. The problem is, then, to seek out the change or changes in the heart muscle that lead to failure, in the hope of being able to reverse them.

My purpose in this paper has been to point out the limitation of the present-day methods of the treatment and prevention of heart disease, to establish the point that this limitation is due to ignorance of certain fundamental factors involved, and to suggest certain promising lines of investigation along which useful advances may be made.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. HERRICK AND BURWELL

Dr. R. H. Halsey, New York: Heart disease is the greatest problem of today from the standpoint of mortality. Heart disease comprises in morbidity from 5 to 8 per cent of the cases that are taken care of every day. All reportable diseases as now reported comprise only 3 per cent; therefore the importance that heart disease bears to the whole problem of morbidity is obvious. An endeavor should be made to get the community heart-conscious and the profession heart-minded for the reason that heart disease is not one disease but a conglomeration of many. In mortality statistics, 7 per cent of the deaths are grouped under three headings and the remainder or, as they are called, "other diseases," of the heart comprise 90 per cent. In other words, etiology is left entirely out of the consideration of what causes death, and as causes of death such things as mitral stenosis or aortic insufficiency, with which many persons live for many years, are put down. A few years ago I sent a questionnaire to all the hospitals of the state, asking three questions: Of those who died in those hospitals, how many died of rheumatic heart disease, how many died of syphilis, and how many died of other diseases of the heart? The replies indicated that out of 30,000 deaths only 2,000 could be accounted for on the basis of etiology. I went to some of the hospitals of New York and asked for the last ten autopsies and then looked for the etiology as stated by the pathologist and the etiology as stated by the clinician. I found that the clinician does not think of etiology in 70 per cent of the cases. The pathologist thinks of etiology in 60 per cent of his cases of heart disease; in other words, in 40 per cent of the cases he does not consider etiology. In that study it was found that, in 1922, 34 per cent of the death certificates assigned the cause of death to chronic myocarditis, while in 1926 they assigned death in 48 per cent of the cases to that cause. That is, the profession became much more myocarditis-minded.

Dr. Emanuel Libman, New York: Clear as the results of any one investigator may be, it is important that a group come together to clear up their differences. There is even no agreement as to what constitutes a normal valve. Bayne-Jones had found vessels in three of fourteen cases. Dr. Gross in his earliest studies rarely had a positive finding. Later he and Kugel found them in 17 of 85 hearts, and still later Ritter, Kugel and Gross reported an incidence of only 2 per cent in

700 hearts. Dr. Gross tells me that he now finds it necessary to adopt still stricter criteria and believes that some of the positive valves were not normal. He believes that some of the reported figures are too high because the muscular wedge is incorrectly considered part of the valve. The important fact is that, whether because of previous disease or not, vessels are present in the valves of a number of individuals, and the relationship of this to the incidence of endocarditis should be ascertained. In taking up this consideration, it is essential to understand an important difference between the conditions that go by the names of rheumatic endocarditis and bacterial endocarditis. Dr. Gross and his associates, particularly Dr. M. A. Kugel and Dr. E. Z. Epstein, have found that rheumatic endocarditis, in contradistinction to bacterial endocarditis, begins in the musculofibrous junction. I shall therefore confine my discussion to bacterial endocarditis and particularly to the subacute form. I believe that it can be taken for granted that the condition can be established and kept up by means of embolism into the valve, and that lesions may also be developed by contact. More must be learned regarding the mechanism suggested by Grant, that the important factor is deposition of thrombotic deposits on rough places and clefts in the valves and their later infection by way of the blood current. To my mind, increased tension is a most important consideration. This would explain the increased incidence of the disease and involvement of the aortic valve during the Great War. The great tendency for bicuspid aortic valves to be involved points the same way. A study of the incidence of vessels in bicuspid valves not the seat of bacterial endocarditis is most essential. If vessels were found in greater frequency in them than in the usual tricuspid aortic valves, a crucial decision could be made. Of fundamental importance is the reduced resistance of the individual and the presence of focal infections. Here lies the main solution of the problem under consideration.

Dr. Fred M. Smith, Iowa City: The coronary arteries were at first regarded as strictly end arteries. At a later stage, opinion varied. Investigation has shown that there is usually extensive collateral circulation. There is still a diversity of opinion concerning the incidence of blood vessels in the valves of the heart. I have never seen any reason why these structures should not be provided with a circulation. The general appearance of many of these vessels would indicate that they were originally present. I question whether they are concerned with the incidence of endocarditis.

Dr. S. Calvin Smith, Philadelphia: Concerning the influence of infections on heart failure, we have all seen toxic patients make brilliant recoveries following the successful treatment of local or systemic infections; the younger the patient and the more recent the symptoms of heart failure, the better are the prospects of relief. But there is no uniformity in results. I am taking less and less stock in the idea that heart failure is precipitated by bacteria or toxins, for, certainly, altered chemistry must first transpire in any bodily tissue before that tissue will allow itself to harbor germs; and it might well be that this antecedent perversion of bodily chemistry also affects the heart, producing primary heart failure in a patient, which failure is not at all due to the secondary presence of remote bacteria. I take exception to the statement that heart failure occurs only in enlarged hearts. Heart failure and heart enlargement need not necessarily be associated in the same patient. I have seen hearts fail that were small and undeveloped; and enlarged hearts, on the other hand, may carry on efficiently for years without failing until the patient eventually succumbs from some other cause. Dr. Burwell mentioned "the difficulty of diffusion through enlarged muscle fibers" as a likely cause of heart failure. Need the muscle fibers necessarily be enlarged to encounter difficulty in diffusion? Could not heart failure also result from a paucity or impoverishment or imbalance of those substances that are to be diffused through heart muscle?

Experience permits the hope that the problem of untimely heart failure, in its earlier stages, will some day be solved through an understanding of heart tissue chemistry. Experience suggests that calcium may early abort some cases of auricular fibrillation; magnesium has seemed oddly effective with occasional patients who have recently developed multiple premature systoles; barium has apparently benefited isolated instances of heart block. In sudden heart failure that produced the abnormality of sharply inverted T waves in an electrocardiogram, some such T waves have turned astonishingly upright following a prompt saturating of the patient with calcium, sodium and potassium. Furthermore, ailing patients with high blood pressure readings, who have been on restricted diets for months, may take a new lease on life when their diet is enlarged —thus perhaps permitting the heart to secure from the more comprehensive dietary those substances which it needed for a physiologic diffusion through heart fibers. And may it not be that, among those heart patients who derive surprising benefits from sojourns amid strange scenes, those benefits are due, in part, to a refurbishment from a new dining table of those as yet unknown substances that diffuse themselves through heart muscle fibers? Indeed, may not the success of some spa-treated heart failure patients be accounted for by the chemical replacement of substances from the spa waters?

Dr. Wallace M. Yater, Washington, D. C.: As one of those particularly interested in the fundamental nature of cardiac failure I should like to emphasize the fact that in a great majority of cases of cardiac failure, except those due to acute myocarditis, or when coronary sclerosis is an important factor, there is practically no microscopic evidence which will account for the failure. Those changes which are found in the nature of fatty degeneration and brown atrophy are undoubtedly late changes. The fundamental nature of cardiac failure of course goes back to cardiac fatigue due to a long continued mechanical strain, whether that strain is due to valvular disease or to increased peripheral resistance. The pathologist has done all that he can to help in the determination of the cause of this fatigue and now it is necessary to turn more to other fundamental sciences, physiology and biochemistry particularly. The main difficulties in the past in the use of these sciences have been that a valvular disease or hypertension could not be reproduced experimentally in animals, and also that chemists have been unable to devise methods whereby small enough quantities of heart muscle could be taken for study so that the efficiency of the heart would not be impaired. Recently Dr. Osterberg of the Mayo Foundation has suggested a microchemical method for the quantitative determination of very small amounts of glycogen in as little as 10 mg. of tissue, so that now there is a way at least to study glycogen metabolism in the heart chemically, and we are endeavoring at Georgetown University to establish a method whereby we can determine by biopsy specimens just what is going on in the dog's heart under varying conditions of physiologic and abnormal activity.

Dr. C. Sidney Burwell, Nashville, Tenn.: Dr. Yater's point with regard to the possible involvement of the dextrose metabolism in fatigue of the heart is extremely well taken. The chief point which I wish to make is that such must be made for all sorts of functional disturbances in the heart muscle. In other words, the statement that heart failure is associated with fatigue of the heart is not sufficient. An attempt must be made to define what is meant by "fatigue," and if this can be defined, something may be done about it.

The Food Man Chooses.—Man's need for food is the same the world over and it must be guided by science and not by feelings. Primitive savages, far from being happy and healthy, are often but struggling for existence. The desire for particular kinds of food was a principal cause of man's migrations, while the food he chose did much to mold his character. Fish eaters from their seaside homes were led to explore the ocean and reaped courage and loved peace and quietness, while the meat eater became the oppressor or ruler, an example of which remains today, the Masai and the Kikuyu. It is shown that the best dietaries of England were in vogue during the seventeenth century, after which the rise of the factory-made products produced gradual deterioration. Similar changes are occurring throughout the tropics with serious results. These are retrograde steps, for by comparing our own with the dietaries of Egypt, Nubia, the Hebrews and other nations, we come to the conclusion that theirs were the better balanced and more adequate.—Leitch, J. N.: *Dietetics in Warm Climates*, London, Harrison and Sons, Ltd., 1930.

ASYMPTOMATIC NEUROSYPHILIS

VI. THE PROGNOSIS OF EARLY AND LATE ASYMPTOMATIC NEUROSYPHILIS[*]

JOSEPH EARLE MOORE, M.D.
AND
H. HANFORD HOPKINS, M.D.
BALTIMORE

Since the demonstration twenty-seven years ago by Ravaut[1] of the fact that the spinal fluid was abnormal in a high proportion of patients with untreated early syphilis, the significance of such abnormalities has been the source of much speculation and debate. On the one hand, it has been contended that these cytobiologic changes were usually transitory, that they tended to disappear spontaneously, and that they were of little prognostic importance. On the other, it is felt that they represent the actual objective evidence of invasion of the nervous system by the spirochete, and that they are the forerunners of clinical neuraxis involvement in later years. So far, little careful work on this major problem has appeared, most of the published papers being based on opinion alone or on the study, often inadequate, of a small number of patients.

We present evidence, from the course of the disease, in 123 well followed and studied patients, which supports the view that spinal fluid abnormalities in patients with early or late syphilis who show no clinical evidence of neuraxis involvement (asymptomatic neurosyphilis) are of grave prognostic import. The space limitations of this paper prevent a discussion of any but the major issue. A subsequent communication will provide further detailed analysis, with a study of collateral factors involved in the transition of asymptomatic into clinical neurosyphilis, such as race, sex, age, duration of infection and influence of treatment, and will also include a survey of the literature.

In a series of papers from this clinic on the subject of asymptomatic neurosyphilis,[2] certain conclusions have been drawn which must be briefly restated. Invasion of the nervous system probably occurs in the majority of all patients with syphilis, and unless the course of the disease is influenced from without (by treatment), this takes place in most instances within the first year after infection. The ability of the invading organisms to produce clinical neurosyphilis probably depends on the defense mechanism of the individual patient. Involvement of the nervous system, when present, can readily be detected in untreated or treated patients by means of routine laboratory examination of the spinal fluid, though in a few instances spirochetes may actually be present in a spinal fluid that is otherwise normal. Abnormalities in the fluid are almost certainly evidence of actual anatomic damage to the nervous system by the spirochete. If the neuraxis escapes invasion at the time of the generalization of the virus during early syphilis, it will not be invaded at a subsequent date (in treated patients) unless a second or later period of general dissemination of organisms and spirochetemia occurs, or unless by direct extension from a neighboring syphilitic focus, as in gummatous osteitis of the skull. Abnormalities in the spinal fluids of patients with late syphilis (excepting neurosyphilis) represent a persistence of changes inaugurated in the early stages of the infection; their lessened incidence in late as compared with early syphilis is due to the fact that by this time a number of patients have developed frank clinical neurosyphilis.

For convenience in study, patients with early or late asymptomatic neurosyphilis may be divided into three groups, on the basis of the character of the changes in the spinal fluid:[3] group 1 includes patients with minimal serologic abnormalities (increased cell count and globulin content, with other tests negative); group 3, those with maximal changes (the paretic formula); group 2, those with fluids of an intermediate type. This classification is adhered to in this paper.

The material available for analysis as to the outcome is shown in table 1. Fifty-five patients whose admission diagnosis was primary or secondary (early) syphilis and sixty-eight with various types of late syphilis, mostly latent, are included. The original examination of the spinal fluid which permitted the diagnosis of asymptomatic neurosyphilis was made either on admission or more frequently shortly after treatment was begun, though in a few instances it was done after a lapse of from one to three years. In such cases the patients were as free from neurologic symptoms and signs as on admission. The absence of clinical evidence of neurosyphilis was demonstrated by a neurologic examination (including an ophthalmoscopic examination) as part of the general physical survey. However, 22 per cent of the patients complained on admission or at the time of spinal puncture of symptoms possibly referable to the nervous system, such as headache, insomnia, nervousness, "rheumatic" pains and weakness; while 28 per cent showed minor neurologic abnormalities, such as dilated, contracted, slightly unequal or irregular pupils, sluggish pupillary light reaction, or slight to moderate exaggeration, sluggishness, or inequality of the reflexes. Careful sensory examinations were not done. In no case was a clinical diagnosis of neurosyphilis permissible at the time of examination of the spinal fluid. The minor symptoms

[3] The spinal fluid of practically all patients in this series has been examined as to cell count, globulin (Pandy's reaction), Wassermann test titered from 0.1 to 1.0 cc. in both water bath and icebox, and colloidal mastic test. No attention has been paid to alterations in pressure, and no emphasis laid on a cell count of less than 10, on a trace of globulin as an isolated finding, or on a colloidal curve showing a reading in all tubes of less than 3. We believe such minor changes to be occasionally present in normal individuals, and often to be due to technical error. Our exclusion of such cases from the classification of asymptomatic neurosyphilis accounts for the discrepancy in our figures and those, for example, of Ravaut or Dreyfus, who find from 60 to 80 per cent of abnormal fluids in early syphilis. A detailed description of the criteria of our groups 1, 2 and 3 is given in the papers named in footnote 2.

and signs detailed may occur in many other conditions than neurosyphilis, or even in normal individuals; and, while their presence has been noted, they have not been regarded as invalidating the diagnosis of asymptomatic neurosyphilis.

The spinal fluid having been found to be positive, the patients were treated in various ways and for varying intervals of time, a detailed discussion of which must await the next paper of this series. Efforts have been made to follow them over considerable periods of time with repeated neurologic and spinal fluid studies; and with a few exceptions (twenty-four cases[4]), these data are available for the whole series over periods of observation ranging from one to nineteen years, and averaging seven years. In many cases, spinal fluid studies and physical and neurologic examinations have been repeated several times over a period of years.

The outcome in early asymptomatic neurosyphilis is shown in table 2, and in late asymptomatic neurosyphilis in table 3. The two series are closely parallel in size, even to the subclassification into spinal fluid groups, and the outcome is closely similar whether the spinal fluid changes were discovered early or late.

Table 2.—*Outcome in Early Asymptomatic Neurosyphilis*

Spinal Fluid in Group	Total Cases	Clinically and Serologically Well	Developed Clinical Neurosyphilis (Definite)	Developed Neurosyphilis (Questionable)
1	6	3	..	3
2	33	23	3	7
3	16	4	4	8

Table 3.—*Outcome in Late Asymptomatic Neurosyphilis*

Spinal Fluid in Group	Total Cases	Clinically and Serologically Well	Developed Clinical Neurosyphilis (Definite)	Developed Neurosyphilis (Questionable)
1	8	3	2	3
2	40	27	2	11
3	20	6	8	6

The subheadings of these two tables need explanation. The patient is stated to be clinically and serologically well only when the final neurologic examination showed no abnormalities (or no minor changes which were not present at the time of the original examination) and the spinal fluid was completely negative at an interval ranging from one to eleven years after cessation of all treatment. He is classified as having clinical neurosyphilis if, at any time during the period of observation, he developed objective neurologic or psychiatric changes which make the diagnosis quite obvious. Under the heading "neurosyphilis questionable" are grouped those patients in whom objective neurologic signs, suggestive but not diagnostic of neurosyphilis, had appeared when they had previously been specifically noted as absent; or when the spinal fluid was still positive (usually unimproved or worse) after treatment though neurologic changes were absent or data regarding them lacking.

The number of patients with group 1 spinal fluids (pleocytosis and globulin increase only) is small, and the fact that two of fourteen patients have developed clinical neurosyphilis and that in six others the present status is questionable does not give a true picture of the ultimate fate of patients with minimal fluid changes. Two factors account for this: the fact that puncture was usually done after some treatment had been given, thus making it almost certain that a number of such cases were missed, because cleared up by treatment; and the fact that unfortunately cell counts have been omitted or lost in many cases studied. Were our material large enough to include all patients who at any time during the course of the infection presented these *minimal* fluid changes, it is certain that the incidence of clinical neurosyphilis would be much lower. In many instances, we have observed that these slight abnormalities disappear rapidly under treatment, though we have omitted such patients from consideration in this series because they have been lost sight of and their ultimate fate is unknown. It is, however, permissible to say that such minimal fluid changes are not necessarily fugitive in nature and of no significance for the future. One patient of this group developed epilepsy at the age of 40 with pupillary and reflex changes indicative of neurosyphilis four years after the completion of inadequate treatment, the spinal fluid being then negative except for the persistence of a moderate amount of globulin. Another died of brain gumma (proved at necropsy) four months after admission, though the admission examination had shown no neurologic abnormalities other than sluggishly reacting pupils. In one patient of this group, the spinal fluid was observed to become spontaneously negative in the absence of treatment, though in two others it was unchanged and in four it became worse in spite of considerable amounts of treatment. The average duration of treatment given to the patients of this group now classified as well was twenty-seven months, while for the patients whose results were certainly or questionably poor it was nineteen months. The average period of observation was six years.

The larger number of patients included in groups 2 and 3 make the results more convincing. Of seventy-three patients with group 2 fluids, 68 per cent are now regarded as well, 6 per cent have developed clinical neurosyphilis, and in 28 per cent the present status is questionable. Two patients in this group, both found to have group 2 fluids shortly after treatment for early syphilis had been started, have developed dementia paralytica, in one case six and in the other eight years after infection. Another has developed early tabes dorsalis, and two diffuse meningovascular neurosyphilis. On the other hand, a surprisingly large number of patients are well after treatment averaging twenty-two months in duration, and over an average period of observation of six years. Two patients of this group have even acquired a probable second infection with syphilis, which is strong presumptive evidence of radical cure of the first infection in spite of the neuraxis involvement. We have observed no instances of spontaneous regression of the spinal fluid to negative in this group; on the contrary, we have repeatedly been impressed with the fact that when puncture is again done in such patients after a lapse following inadequate treatment, the fluid changes are invariably either unimproved or more usually worse.

That the paretic formula in the spinal fluid, even in early syphilis, is of extremely grave prognostic significance is shown by the outcome in the thirty-six cases falling into group 3. Here, even in the relatively brief average period of observation of eight years, only 27 per cent of the patients can be regarded as clinically and serologically well. Thirty-three per cent (twelve patients) have developed clinical neurosyphilis, and in 40 per cent the present status is questionable. No less than seven patients in this small group have already developed dementia paralytica, and three tabes. The gravity of the situation is further exemplified by the fact that the average duration of treatment necessary to accomplish a satisfactory clinical and laboratory result in this group was nearly twice as long—forty months—as in patients with groups 1 or 2 fluids; and in many instances, tryparsamide or fever therapy or both, rarely resorted to in patients of the other two groups, were necessary.

---

[4] These twenty-four patients include six in whom final neurologic examinations are available but repeat spinal fluid examinations are lacking; and eighteen in whom the reverse is true. In all other patients, statements as to the ultimate outcome are based on reexamination from both clinical and laboratory standpoints (blood Wassermann and spinal fluid tests) at the end of the period of observation.

Table 4.—*Types of Clinical Neurosyphilis Observed as Sequelae of Asymptomatic Neurosyphilis*

Admission Diagnosis and Group of Asymptomatic Neurosyphilis		Developed Clinical Neurosyphilis, Type						
		Total Cases	Dementia Paralytica	Tabes Dorsalis	Diffuse Meningovascular	Vascular	Epilepsy	Died, Neurosyphilis
Early	1	..	..	..	..	..	..	..
	2	3	2	..	1	..	..	..
	3	4	2	1	1	..	..	1
Late	1	2	..	..	..	1	1	1
	2	2	..	1	1	..	..	..
	3	8	5	2	..	1	..	3

In table 4 may be found a summary of the clinical types of neurosyphilis observed to develop in patients with early and late syphilis, further subdivided as to spinal fluid groups. It is a curious fact that parenchymatous neurosyphilis (dementia paralytica and tabes) was by far the most frequent type of neuraxis involvement observed (thirteen of nineteen cases) though as one sees the manifestations of neurosyphilis on the admission of untreated or badly treated patients, the meningovascular type predominates in the proportion of 2 to 1. This can hardly be due to any other cause than that the large majority of patients in this series were well and intensively treated, comparatively speaking, after the discovery of the spinal fluid changes; and that such intensive treatment is effective in preventing the development of meningovascular, but not of parenchymatous, neurosyphilis. This table further brings out the fact that, while one cannot assure a patient whose spinal fluid is of the group 2 type that he will not develop tabes or dementia paralytica, his chance of doing so is markedly less than when his original spinal fluid changes are maximal in degree (group 3). The opinions we have previously expressed,[2] that the foundations of dementia paralytica and tabes are laid in the early days of the infection and that patients with group 3 (paretic formula) fluids are candidates for parenchymatous neurosyphilis, seem amply confirmed by these figures. Of the twelve patients with group 3 fluids who subsequently developed neurosyphilis, the type of involvement was parenchymatous in no less than ten, of whom three were admitted with early syphilis. The point is worth mentioning that, to be of real prognostic value, a spinal fluid examination must include a quantitatively titered Wassermann reaction and a colloidal test, since the presence or absence of the paretic formula cannot be detected without them. The omission of these two tests invalidates much published work, especially from abroad.

We feel that the figures we have given as to the outcome of asymptomatic neurosyphilis, while convincing enough, nevertheless present the matter in its most favorable light because of the relatively short period of observation possible in most instances. Keeping in mind the facts that routine spinal fluid examinations have been in use in our clinic for a little less than ten years, and that the average interval between infection and the development of parenchymatous neurosyphilis, for example, is from twelve to fifteen years, it is obvious that further observation will be necessary to settle the fate of most of our patients now classed as questionable. This is amply illustrated by table 5, in which is shown the basis of the "questionable" classification. Of thirty-eight cases so classified, the spinal fluid at the last examination, usually after considerable amount of treatment, was still positive (usually unimproved or worse) in thirty-one. Nine of these thirty-one have developed since admission minor neurologic changes suggestive, but not diagnostic, of neurosyphilis; in twelve, no such objective changes have appeared; and in ten, recent neurologic examinations have not been done. Seven patients are classified as "status questionable" on the basis of the appearance of minor objective neurologic signs, though in six of these the spinal fluid is now normal (in one case spinal fluid data are lacking). It seems too much to hope that many of the thirty-one patients whose fluids are still positive will escape clinical neurosyphilis.

Eleven patients of this series are dead. Four died of dementia paralytica, one of cerebral gumma. One patient with a group 2 fluid died at the age of 38 of a cerebral vascular accident, but since he had a severe hypertension, and since a necropsy was not obtained, he is classified with the questionable group. Two died from cardiovascular syphilis, one of whom had definite signs of tabes before death. Three have died of causes unrelated to syphilis, of whom one had developed internal ear deafness (cochlear nerve paralysis) as clinical evidence of neurosyphilis before death.

Since we have laid so much stress on the grave prognostic import of asymptomatic neurosyphilis, the question will inevitably be raised as to the prognostic significance of negative spinal fluid observations in early and late syphilis. In general, it may be stated that if the spinal fluid, examined at an appropriate time in a patient undergoing treatment for early syphilis, is negative, and if the patient completes modern treatment requirements with no clinical or blood Wassermann reaction relapses, reexaminations of the fluid at subsequent dates will be negative; and, excepting the possibility of a more or less purely vascular neurosyphilis, the development of clinical neurosyphilis, especially of the parenchymatous type, is extremely unlikely. In late syphilis, even the quali-

fications as to treatment and the time of spinal puncture are unnecessary; a negative fluid will remain negative and, with rare exceptions, the patient will not develop neurosyphilis. Data supporting these statements will be provided in a separate communication.

SUMMARY AND CONCLUSIONS

1. Data regarding the outcome of 123 patients with asymptomatic neurosyphilis (including 55 whose admission diagnosis was early and 68 late syphilis) observed over an average period of seven years are presented. Conclusions are based on repeated clinical and spinal fluid reexaminations.

2. The patients are classified in three groups (1, 2 and 3) on the basis of the intensity of the spinal fluid changes.

3. Spontaneous regression to normal of positive spinal fluid observations of any degree of intensity is a rare phenomenon.

4. Of 14 patients with group 1 spinal fluids, 6 are clinically and serologically well, 2 have developed clinical neurosyphilis and in 6 the present status is questionable.

5. Of 73 patients with group 2 fluids, 50 are clinically and serologically well, 5 have developed clinical neurosyphilis (of whom 2 developed dementia paralytica and 1 tabes), and in 18 the present status is questionable.

6. Of 36 patients with maximal (group 3) fluid changes, only 10 are well. Twelve have developed clinical neurosyphilis (of whom 7 developed dementia paralytica and three tabes), and in 14 the present status is questionable.

7. The presence of a group 3 spinal fluid, early or late in the course of syphilitic infection, is strong presumptive evidence of liability to the development of parenchymatous neurosyphilis.

8. Since the average observation period is short, it seems certain that the figures given for the incidence of clinical neurosyphilis are minimal and that from the 38 patients now classified as "status questionable" further examples will develop.

9. Eleven patients of the series are dead, of whom 5 died of neurosyphilis.

10. The presence of a positive spinal fluid in patients with early or late syphilis who show no objective neurologic abnormalities is of grave prognostic import. Generally speaking, the ultimate danger to the patient is roughly proportional to the intensity of the spinal fluid changes.

11. On the other hand, a negative spinal fluid in early or late syphilis is, subject to certain qualifications, a practical guarantee of safety for the future so far as the development of neurosyphilis is concerned.

12. These facts being true, routine spinal puncture is an indispensable part of the management of every patient with syphilis.

101 Richmond Street—1400 Eutaw Place.

ABSTRACT OF DISCUSSION

Dr. Udo J. Wile, Ann Arbor, Mich.: The figures just presented are an adequate justification for the use of lumbar puncture in the early weeks of this infection, when patients are seen for the first time. The results we have obtained in our cases, extending over eighteen years, are practically identical with those that have just been presented. In 1914, Dr. Stokes and I suggested that the fate of every patient with syphilis, as affecting his central nervous system, was decided within the first few weeks of his infection. We are certain that that statement must be taken with some qualification. It should be remembered that the criteria of "normal" in the spinal fluid are entirely arbitrary. Between the arbitrary "normal" and the abnormal, which is a small gap, things may occur which cannot be detected with the present criteria of diagnosis. I differ slightly in regard to the criteria suggested here. I should like a definite distinction between invasion and involvement. Invasion of the cerebrospinal axis must be accepted as occurring in all cases. Perhaps it is best to accept the probability that in all cases of syphilis a cerebrospinal enanthem is being dealt with. Involvement of the nervous system means an entirely different thing. If involvement occurs in from 5 to 10 per cent late and in from 20 to 30 per cent early, and invasion occurs in 100 per cent, a transitory phenomenon in clinical observations must be present, which does not come to the foreground. The second point is including in this group of asymptomatic cases those cases in which headache or other abnormal conditions, including inequality of the pupils, are present. It is precisely in the group in which clinical symptoms are more than suggestive that experience tells me that cerebrospinal disease does occur. I should like to hear more from the authors as to why they include in this group cases that they regard as asymptomatic which would ordinarily be regarded as involvement and not as invasion. The last point of interest is the relation of cases that have a serious type of involvement early to the type that shows development of cerebrospinal disease late. Generally speaking, I think those cases that present severe parenchymatous changes early are those that are headed for severe disease later on.

Dr. Paul A. O'Leary, Rochester, Minn.: I believe the majority of syphilotherapists are familiar with the fact that most of the patients with asymptomatic neurosyphilis when treated intensively obtain satisfactory serologic reversals. I make mention of this because I failed to gather from the report of Drs. Moore and Hopkins the percentage of good therapeutic results noted in their study. In my experience approximately 90 per cent of these asymptomatic cases respond favorably to treatment. One of the chief difficulties in the care of these patients is to determine when the patient with asymptomatic syphilis should no longer be classified as asymptomatic. In other words, when shall the diagnosis, for example, change to paresis sine paresi? In addition to the persistently positive spinal fluid or the frequent relapses from negative to positive, the colloidal benzoin test is a valuable prognostic index. When it has been possible to repeat the test frequently, I have found it not only more stable but also more reliable in the recognition of the paretic curve than the colloidal gold solution. In the 10 per cent who fail to show serologic response to treatment and are in the process of developing asymptomatic dementia paralytica, malaria therapy remains the outstanding therapeutic agent in my experience. The observations reported two years ago from my clinic have been substantiated by subsequent study of a larger group of similar cases. In fact, it is my belief that the ideal indication for malaria treatment is found in the patient with asymptomatic neurosyphilis who has had intensive courses of intravenous and intramuscular therapy but in whom the spinal fluid remains positive and the colloidal benzoin curve continues to be of the paretic type.

Dr. Joseph Earle Moore, Baltimore: Dr. Wile has put his finger on one crux of the situation with reference to the classification of this material as asymptomatic neurosyphilis, and comments on including in this group patients who actually had syphilis and actually had neurologic signs. That was done for two reasons: first, because the symptoms of which these patients complained were symptoms of which normal individuals may complain. Headache is a common symptom; rheumatic pain; weakness, nervous irritability, insomnia, and so on are things from which all of us suffer and from which patients with negative spinal fluid as well as positive suffer particularly. We have already published a small number of figures bearing on this point and will in the future expansion of this work produce more, but we feel that it is quite impossible to make diagnoses of central nervous system syphilis on such complaints as this. The question of minor neurologic signs, including sluggish reflexes, unequal pupils and so on, are perhaps more important; but these phenomena also occur in normal individuals who do not have syphilis, and also frequently in syphilitic patients who do not have positive spinal fluid, so the same situation may be said to exist with reference to physical signs as with syphilis. We find ourselves unable, even with the assistance of our neurologic department, to make definite diagnosis of syphilis in a patient who comes in complaining only of headache, sleeplessness, weakness, or inability to concentrate, and such patients are excluded from a definite clinical diagnosis of central nervous system syphilis. Dr. Wile's point regarding the ultimate outcome is well taken. The point was mentioned that because a patient does not show the paretic formula early in the course of the infection he will not develop dementia paralytica; but if this is shown I think the chances of his developing dementia paralytica are much greater than if he does not show it and, conversely, he is much less likely to develop the disease if he does not show it. Dr. O'Leary asked about the percentage. In summary I may say that in group 1, of fourteen patients six are serologically and clinically well; in group 2, good results were obtained in approximately 50 per cent of the cases, while in group 3 only about 10 per cent are symptomatically well. The rest of the fluids are definitely syphilitic, emphasizing again the great importance of the paretic formula early or late in the course of the infection.

THE SEQUELAE OF BILIARY TRACT INFECTION *

JOHN B. DEAVER, M.D.
PHILADELPHIA

The biliary tract, composed of branching channels of various sizes, is greatly dependent for its normal well being on the free onward passage of its contents. The consequences of obstructed bile flow have to do largely with impairment of liver function. In a clinical sense, bile obstruction and infection are practically always coexistent and in nearly every case infection is the primary cause. Cholecystitis causes interference with the normal emptying of the gallbladder, and the resultant bile stasis is favorable for the formation of stones. With few exceptions infection is the primary lesion, to which is added later the complication of gallstones. Pathologic studies have shown that in the early stages the infection begins in the submucosa, as manifested by congestion, edema and round-cell infiltration. This process extends outward to involve the muscularis and serosa and inward to affect the mucous membrane. The crypts and glandular pockets become distended with bile and mucus and extend their depths farther into the wall of the gallbladder until in some cases they actually lie just beneath the peritoneal covering. Stones may form in these pockets and lead to perforation of the gallbladder. The inflammatory condition usually goes on to spontaneous resolution, but in so doing it leaves a deposit of fibrous tissue which causes the wall of the gallbladder to become thickened and less flexible. The quiescent infection in the wall of the gallbladder is prone to undergo many exacerbations, each one leaving in its wake more structural deformity and functional impairment. Eventually the gallbladder becomes a harbor of infection and a site of fomenting potential mischief for its neighboring structures. The sequelae of biliary tract infection now assume major importance through neglect to deal promptly and properly with the original lesion.

The consequences to the gallbladder itself are important. It becomes a useless organ and a factor in the formation of adhesions to neighboring structures. Such adhesions, particularly to the stomach and duodenum, are a source of annoyance to the patient and of confusion to the diagnostician. In many instances the roentgenologist is unable to distinguish between the deformity of the duodenum caused by ulcer and that by adhesions. The clinical picture may be suggestive of either lesion. In fact, even when the abdomen is opened the surgeon may experience considerable difficulty in determining whether the original lesion is in the duodenum or in the gallbladder. Pericholecystic adhesions may have their attachments not only to the duodenum and pylorus but also to the hepatic flexure of the colon and the great omentum, and not infrequently the dilated pelvis of the gallbladder is adherent to the right free border of the gastrohepatic omentum along the line of the common duct. Unless the adherent pelvis is carefully dealt with and carefully separated and the structures are identified, either the common or the hepatic duct or both ducts may be injured, the possible serious consequences of which are well known.

Perforation of the gallbladder may occur into the free peritoneal cavity through the action of ulceration and the pressure of stones. This usually fatal catastrophe fortunately is rare. More commonly, adhesions will attach the gallbladder to one of the neighboring hollow viscera, such as the stomach, duodenum or colon. When perforation occurs, the result is the formation of an internal biliary fistula. Judd and Burden, who have reported 153 cases of internal biliary fistula, conclude that: "Internal biliary fistula is a late complication of cholelithiasis. It rarely occurs in the absence of calculi. The organs involved and the order of frequency are duodenum, colon and stomach. The fistula is nearly always by direct communication; only rarely is there an intervening abscess cavity. The symptoms are characterized by long duration and severity. Diagnosis is usually made only at the operating table. Formation of a spontaneous biliary fistula is in no sense a cure of cholelithiasis, but is an addition and dangerous complication. The treatment of the condition when found is closure of the fistula, cholecystectomy when possible, and careful exploration of the ducts for stones. Emergency drainage of the gallbladder and ducts may be the only logical procedure in some cases. Separate lesions in the stomach or duodenum may be complicating factors. The unnecessarily high operative mortality is a direct result of delay of the patient in coming to operation."

Carcinoma of the gallbladder is not a very uncommon sequel. It may be designated as a late complication of cholecystitis in which gallstones have been the inciting factors. The rôle of irritation in the pathogenesis of cancer is self-evident. The constant local irritation of stones in the gallbladder leads to proliferation of cells which may in time overstep the mark and spread beyond the bounds of usefulness and repair. When this stage is reached, cancer is established. The symptoms of malignancy of the gallbladder do not differ materially from those of cholelithiasis. The diagnosis is rarely made before operation, and at operation the condition found is usually so far advanced that it is beyond the hope of remedial measures. Carcinoma of the gallbladder does not always develop in ancient gallstone disease; but when it does, the reason, I believe, is to be found in individual susceptibility. In other words, the development of a carcinoma under such circumstances depends on two factors: individual susceptibility and the irritation that provokes proliferation.

---

* Read before Section on Surgery, General and Abdominal at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

When the function of the gallbladder is lost or impaired through disease or by removal, there follows a dilatation of the extrahepatic bile ducts which apparently is caused by intermittent contraction of the sphincter of Oddi. After a time the sphincter becomes incompetent and bile flows continuously into the duodenum but the ducts remain permanently dilated. The mechanism of the sphincter of Oddi, its normal and abnormal function, afford a splendid field for investigation into the etiology of biliary tract disease. I believe that therein will be found the explanation of many postoperative phenomena and symptoms which at present are not understood. In operations on the biliary tract it is my routine practice to make a thorough examination of the common duct. When there has been a history of jaundice and the common duct is dilated and thickened, I always make an exploration of its interior by the use of probes and also with the finger if possible. I am not satisfied that this exploration has been complete until an instrument can be freely passed into the duodenum. In many cases the value of this procedure has been demonstrated by the finding of a contracture or an actual stricture at the terminal portion of the common duct, through which considerable force was required to pass the instrument into the duodenum. Contracture of the termination of the common duct may be due to inflammatory stricture, to pressure from inflammation in the head of the pancreas, and to spasm of the sphincter of Oddi. These conditions cannot always be differentiated and their frequency makes it imperative for the surgeon to be certain of the free patency of the duct. A number of German surgeons have advocated and carried out dilation of the distal end of the common duct by the use of graduated probes in every case in which exploration of the duct has been advisable. I believe that if more attention were given to this source of disturbance many of the postoperative sequelae of biliary tract disease would be eliminated.

The effects of cholecystitis on the liver have occupied my attention for some time. While I am not yet entirely satisfied as to which is the primary disease, I am inclined to believe that in the majority of cases the original lesion is in the gallbladder. There are probably some cases that begin as a diffuse infection of the biliary tract which later becomes localized in the gallbladder and the adjacent portion of the liver. But my surgical experience has convinced me of the pernicious effect which chronic cholecystitis has on the structure and function of the liver and that the best results in these cases are to be obtained by the removal of the gallbladder before the hepatic damage has become irreparable.

A potent reason for assigning to the gallbladder the primary rôle in the production of hepatitis lies in the fact that in the mild cases of cholecystitis the involvement of the liver is limited to a small area immediately adjacent to the gallbladder. In cases of longer duration the hepatitis is more diffuse and deep seated. It is especially noticeable in the anterior border of the liver, which is sometimes thickened to as much as from 8 to 10 cm. The entire liver is often enlarged, friable and has the appearance of intense congestion. It seems logical to believe that prolonged diffuse infection of the liver as it is seen in hepatitis will eventually lead to biliary cirrhosis. The latter condition favors congestion and enlargement of the spleen so that to obtain a cure in these long standing cases it is sometimes necessary to remove the spleen and the gallbladder, and to secure external biliary drainage by the use of a T-tube inserted in the common duct.

Infection may reach the liver through the blood stream, through lymphatic spread from an infected gallbladder and by way of conduction along the bile duct, as an ascending cholangeitis.

Cholecystitis and cholangeitis frequently are associated lesions. Studies of this condition, notably the study of Burden, show the presence of inflammatory changes in the walls of the common duct in every case of chronic cholecystitis. These inflammatory changes seem to follow along branching glandular channels which have a widespread distribution throughout the entire duct system. They afford a ready means of dissemination and infection. The inflammatory process is characterized by round-cell infiltration, of cystic dilatation of the mucous glands, deposits of fibrous tissue and thickening of the walls of the duct. It may extend upward and involve the smaller ducts of the liver and become a cholangeitis. This deep-seated interstitial infection of the walls of the duct not only encourages chronicity but makes difficult any successful therapeutic attack. The only rational therapeutic procedure is removal of the focus of infection, which is usually the gallbladder, and the maintenance of free drainage of bile by the introduction of a T-tube into the common duct. Choledochitis is a cause of stricture, a lesion that occurs most frequently at the junction of the cystic and common bile ducts in a region where choledochitis is most pronounced as a secondary lesion of cholecystitis. In these cases of inflammatory narrowing of the duct, removal of the gallbladder may be followed in several months by the development of obstructive jaundice caused by formation of a stricture. Needless to say, secondary operations for this condition are formidable, attended by great immediate danger and often by unsatisfactory postoperative results and a long convalescence.

Stricture of the common bile duct or the hepatic duct may be primary, but most often it follows some surgical procedure on the biliary tract, although the operation is not necessarily the cause of the stricture since the healing of the inflammatory lesion along the duct may result in the formation of scar tissue with serious interference with the lumen of the common duct. In a certain percentage of cases the stricture has been caused by operative injury to the duct, particularly in the region of the junction of the cystic and common ducts. It is of the utmost importance for the surgeon to be absolutely certain of his identification of the structures during operation because it is the only method that offers assurance against operative injury. A word of caution should be mentioned regarding efforts to ligate the cystic duct flush with the common duct during cholecystectomy. To do so is unwise and unnecessary. Although leaving a small stump of the cystic duct may not be objectionable, efforts to remove it completely may seriously compromise the lumen of the common duct. Another possible cause of stricture is the introduction of gauze packing in too close proximity to the common duct. This may result in the excessive formation of scar tissue and stenosis of the duct. The symptoms of stricture of the common duct are jaundice and pain; the jaundice is intermittent in character and is usually preceded by an attack of colic, so that the symptoms closely resemble those of stone in the common duct. Operative injury to the duct usually results in a biliary fistula, spontaneous closure of which is followed by the development of constant, complete jaundice.

The sequence of events from cholecystitis to pancreatic lymphangitis and chronic pancreatitis has lost none of its significance, to me at least, during the course of my experience since my interest was first aroused in this pathologic process. I see it often enough to confirm my stand, not only at operation but in the follow-up clinic, where failure to obtain complete relief from upper abdominal symptoms is plainly due to a chronic pancreatitis. Regional lymph node involvement in cholecystitis is very much like cervical adenitis caused by tonsillitis or by inguinal adenitis in an inflammation of the lower extremity. As the original inflammation subsides by treatment or by removal of the focus of infection, the adenitis usually subsides. Unfortunately, the pancreas, when seriously affected, undergoes fibrotic changes which remain as a potent cause of trouble. Since there is no direct way of attacking the pancreas, the treatment of pancreatitis is essentially prophylactic; that is, treatment of the biliary tract infection before the pancreas has become involved by destructive inflammation. It is my belief that a certain percentage of cases of diabetes are caused by pancreatic changes which result from cholecystitis. Certainly, the frequent association of disease of the biliary tract and potential diabetes as shown by the high sugar content of the blood is not a mere coincidence.

While most practitioners are aware of some of these local effects of gallstone disease, I have thought it worth while once more to call attention to the familiar as well as to the less familiar sequelae of biliary tract infection. Constant dripping wears away the stone (though not the gallstone) and constant reiteration may wear away the delusion that too much attention is being paid to disease of the gallbladder and its local and remote effects. The latter need as much emphasis as the former, for the rôle of the gallbladder as a focus of infection is not sufficiently in the consciousness of the average diagnostician. The occurrence and character of the manifestations secondary to a focal infection are dependent on the number, virulence and specific action of the bacteria. The degree of tension in the focus is due to the mechanical obstruction to normal drainage and the vascularity of the focus. These, I believe, are the generally accepted facts with regard to the relationship of focal infection to local and systemic disease. Since in its structure the gallbladder admirably complies with these requirements for the rôle of a focus of infection, it is rather surprising that its part in systemic disease was not earlier suspected and has not been more generally conceded. The infective agent often is the streptococcus, which, as is well known, has a special affinity for certain tissues, such as the fascial planes, the joints, the heart muscles and occasionally the kidneys. The frequent presence of streptococci in the walls of the gallbladder and in gallstones is demonstrable evidence that certain systemic symptoms can be directly referable to a cholecystitis or a cholelithiasis. It is therefore not unusual nor surprising to find that some of these patients complain of attacks of rheumatism and develop painful nodules in muscular planes, while others show myocardial symptoms, dyspnea and palpitation on slight exertion, the fear of which leads to a certain inertia which in turn creates a tendency to the fair, fat and forty type of individual and adds the danger of fatty cardiac degeneration to the myocarditis. Occasionally rheumatoid arthritis, and sometimes disease of the kidneys, may be traced directly to an infected gallbladder. Again, I say, these are not theories but facts borne out by my own experience and the experience of others, that with the removal of the gallbladder the systemic disease is cured or at least very much relieved provided, of course, that the damage already done is not irreparable. Therefore I say, "Ever bear in mind the insidious streptococcal infection lurking in the wall of the gallbladder."

Myocardial disease has long been recognized as a lesion which is frequently associated with cholecystitis. Many years ago, Kerr emphasized the causal relationship between these two lesions. My experience certainly confirms this observation. In fact, myocardial disease is a prominent cause of death after operations on the biliary tract. In many cases the infection in the gallbladder is no doubt responsible for the myocarditis. In other cases the development of the two lesions is favored by the constitutional make-up of the individual. Nevertheless, it must be recognized that myocarditis may be a sequel of cholecystitis and that the possibility of this complication merits serious consideration on the part of those who counsel delay in the surgical treatment of biliary tract disease.

From their medical colleagues, physicians hear much about adhesions following operation on the biliary tract. I am admittedly and without reservation an advocate of early surgical treatment of biliary disease. A long experience has convinced me of the evil consequences of delay. The results of surgery are by no means perfect and especially in the region of the right upper quadrant of the abdomen, which contains so many important structures. Surgical intervention when made at a late hour cannot be expected completely to restore the condition to normal. Adhesions more or less follow every abdominal operation, but rarely do I find that they are the actual cause of symptoms. In cases of severe disease in the right upper quadrant of the abdomen, as in suppurative cholecystitis, nature forms dense adhesions which often make it extremely difficult for the surgeon accurately to identify the structures. Such adhesions cannot completely be corrected by any type of operation; in fact, it is the part of surgical wisdom to disturb them as little as possible to accomplish the desired operative procedure. It seems to me an unfair criticism of surgery of the biliary tract to ascribe postoperative symptoms directly to the operative procedure with the implication that had the operation not been done the patient would not have the symptoms. Surgical errors do occur and sometimes they make the last condition worse than the first; but, as a surgeon, I am happy to state that such occurrences, fortunately, are rare and relatively infrequent.

The symptoms of chronic cholecystitis, with the exception of colic, are largely those of a reflex gastric disturbance commonly spoken of as gallstone dyspepsia. I believe that most of these gastric symptoms are caused by pylorospasm and that many of the postoperative complaints are also due to pylorospasm. Clinical and experimental studies have well established the irritability and dysfunction of the pyloric sphincter in cases of abdominal irritation. Pylorospasm, which has long persisted as a reflex phenomenon of chronic cholecystitis, leads to hypertrophy of the pyloric sphincter, which I am able frequently to demonstrate at operation. For the purpose of correcting this condition and avoiding postoperative symptoms it has recently been my practice, in operations on the biliary tract in cases showing pronounced gastric symptoms, to remove the anterior half of the pyloric sphincter. This added procedure is easily carried out in a short time and without an opening into the lumen of the intestine. The technic has been described in previous publications concerning the treatment of peptic ulcer. The procedure eliminates the pyloric sphincter as a factor in postoperative complaints and has been attended by satisfactory results.

In this paper I have included only the more important sequelae of biliary tract infection in which the gallbladder has been considered as the center of attention. Some of the sequelae of cholecystitis are loss of the function of the gallbladder, dilatation of the common duct, insufficiency of the sphincter of Oddi, gallstones, choledochitis, cholangeitis, hepatitis, biliary cirrhosis, pancreatic lymphangitis, chronic pancreatitis, carcinoma of the gallbladder, myocarditis, focal infection and pylorospasm. Consideration of this array of diabolic forces should be sufficient reason to make one appreciate the serious potentialities of infection of the gallbladder. To me there seems no valid reason to withhold the help that surgery can offer. Improvement in surgical end-results will follow earlier intervention, that is, before the sequelae of biliary tract infection have become established.

1830 Delancey Place.

ABSTRACT OF DISCUSSION

Dr. William D. Haggard, Nashville, Tenn.: To Dr. Deaver more than to any one else belongs the credit for teaching that pancreatitis is largely of lymphatic extension from the gallbladder. Opie described a postmortem in which the gallstone was lodged in the ampulla of Vater and mechanically retrojected the bile into the duct of Wirsung. I have never encountered a facsimile of it. Robson called attention to a fact that with a pancreas so hard and enlarged as to be mistaken for carcinoma, when the gallbladder was removed for associated gallstones, although the surgeon thought the condition was malignant and gave a grave prognosis, he found that the tumor disappeared and the patient got completely well. That was the experience that ushered in the clinical recognition of chronic pancreatitis. Not all cases of chronic pancreatitis are cured by cholecystectomy. In such cases, Dr. Deaver has shown that prolonged drainage of the common duct, even as a secondary operation, if necessary with the T-tube, is curative. The sequelae in reference to other organs are extremely interesting. Willius showed that 54 per cent of cases of cardiovascular disease associated with gallstones were greatly benefited by the removal of the gallstones. A considerable number of anginoid cases were benefited, and in those who were not relieved, the attacks were modified, were much less in severity, and greatly ameliorated. One does not have the same excellent result with myocardial disease from removal of the gallbladder as a focus as from an arthritis and "lumbagos" in a child, for instance, with enlarged tonsils. The arthritides with associated gallbladder disease are likewise not so definitely and uniformly benefited. The streptococcus is a notoriously chronic type of micro-organism, and when the arthritides have that origin, the fascial planes are a long time getting over the infection. Moreover, whatever focus started the streptococcus, the gallbladder and the heart or the joint were probably hit at the same time. The cases of carcinoma of the gallbladder from gallstones formerly numbered about 5 per cent. They are always associated with gallstones. At the present time, as the result of the universal and successful practice of removing the gallbladder early, and nearly half of them without gallstones but with a chronic, infectious, intramural cholecystitis, the incidence of carcinoma has been reduced to such an extent that it is probably not over 1 per cent. The question, therefore, may well be asked: What does it profit a person to carry around gallstones that have a potential likelihood of production of cancer of 1 per cent when removal of the gallbladder probably would carry much greater mortality? In reference to all these sequelae, I think this may be said: It has been my practice for a number of years in selected cases of primary acute cholecystitis, diagnosed early, to treat then and there by operation in the beginning.

Dr. Clark D. Brooks, Detroit: I recall about twenty years ago visiting Dr. Deaver's clinic in Philadelphia. He had a difficult gallbladder case presenting stones in the hepatic and common ducts. After a few minutes he succeeded in getting the gallstone from the common duct and I remember his remark as he held it up: "Oh, if I could only have had you nineteen years ago!" Of course, the patient had complications, simply because of this long-standing infection. Regarding the sequelae of biliary disease, I believe that operation should be performed as early as possible. However, one must be sure of the diagnosis. In addition to the clinical symptoms, one should use the Graham test as a diagnostic acid, when the opportunity affords itself. It is not felt in our clinic that the examination is complete unless we have used the Graham test. We use the oral method, and 97 per cent of the cases diagnosed by this procedure have been correct. There is not time to say much about the cases of calculous and noncalculous gallbladder. They cause different symptoms. In cholecystitis of the noncalculous type, when the symptoms are not relieved by medical treatment, after a few months, surgery is indicated. The longer the delay in the medical treatment, the greater the complications and the higher the mortality. It is well known that many heart attacks are relieved by surgical intervention in an infected gallbladder. Not infrequently the patient with common or cystic duct obstruction and a distended gallbladder will suffer attacks of cardiac irregularity, which are entirely relieved by surgical drainage. The obese patient and the aged patient are not fit for any extended operation, and when possible several days of careful preoperative treatment is all important. For over two years I have used spinal anesthesia. I think it is the most satisfactory anesthetic I have ever used in operations on the biliary tract. By doing choledochotomy one can remove the gallbladder and drain the ducts. I believe that if more of the so-called duodenal drainage tubes were cut up in sections 8 inches long and put in the cystic or common ducts and left there several weeks, instead of used to tickle the esophagus, many patients would be alive today.

Dr. F. F. Lawrence, Columbus, Ohio: Dr. Deaver's exposition reminds me that there are four questions every surgeon must answer: What, why, how and when? What and why will ever remain for scientific and abstract determination. The how depends on the surgeon's training and personal preference. Why does biliary tract infection occur, to begin with? Why do these sequelae of which Dr. Deaver speaks occur? In order to get a clear conception of the picture, the anatomy of the lymphatics must be reviewed. According to Sappey and Poirier, the lymphatics of the pelvis and abdomen come up along with the branches of the portal vein to their junction, and a short distance after they join to form the portal vein become embedded in the wall of the portal vein, enter the liver and break up there, forming intralobular, sublobular and interlobular branches, the same as the vein does. Then, in every case of biliary tract infection one can get a history of typhoid infection, pelvic infection or appendicitis. If this infection comes from below, and if the bile tract, lymphangitis and lymph nodes which remain as sequelae are really antecedent, they exist because the infection has been taken up from the chronic appendicitis, the pelvic infection, the typhoid ulcer or elsewhere, and carried up. But the infection was in the lymph vessels and lymph glands first, and they became lymph nodes. Why, then, does the septic cirrhosis occur? Because of delay or improper drainage. If the infection should be primarily in the substance of the liver in the small secretory ducts of the liver and in the bile tract second, if that infection was not drained out this septic cirrhosis of the liver might be expected to develop. Why does the splenitis occur which has sometimes been thought Banti's disease and a splenectomy performed therefor? Because of the portal obstruction damming back the blood on the spleen. Nobody has ever seen a pathologic examination of the spleen under any such condition, or after death, in which anything but venous engorgement was shown.

Dr. E. Payne Palmer, Phoenix, Ariz.: Chronic cholecystitis is a surgical disease, amenable only to surgical treatment and should be so treated as soon as the patient can be prepared for treatment. One should not wait until next week or next month or next year. I do not think that the surgeon needs so much educating in cholecystitis as the internist, the gastroenterologist and the general practitioner, and surgeons advise the patient to wait until next week or next month, or maybe next year, to see what the result will be. I have had to treat two cases of intestinal obstruction as the result of a spontaneous cholecystoduodenostomy having occurred and large gallstones passing down into the intestinal tract producing the obstruction. I think that the importance of postoperative care should be stressed. If the patients are sent away with the idea that they are cured, there are going to be failures and the results will not be nearly so satisfactory as if one turns them back to a good internist or to their home practitioner with the idea that the treatment must be carried on for a long period.

DR. WILLIAM J. CASSIDY, Detroit: The great question in the procession across the surgical arena is one which has taken place in the last twenty years, which has made surgery so safe that the abdomen has been opened in a multiplicity of instances with impunity and many diagnoses have been based on symptomatology which does not bear the searchlight of accuracy at the time it is opened up. Many innocent gallbladders, or gallbladders with a few little cobwebs around them, are raised to the pinnacle of a terrific disease. This is the situation today. I have no quarrel with the surgeon who wants to remove or drain a gallbladder when he can show that it is infected, but I have a great deal of antipathy to the surgeon who opens every abdomen because the patient has a few little swallows of gas, whose diet has never been regulated, and nothing has been done previous to that time. I don't care how expert the surgeon is, if he does not regulate the patient after operation and regulate his home environment, he has done him absolutely no good by taking his gallbladder out. Dr. Lawrence hit the nail on the head. He said that the infection in the lymphatic stream went up into the liver. What is done surgically? The gallbladder is taken out and this large mass of ducts all through the liver, the common duct, the cystic duct and the head of the pancreas, which can't be taken out, are left. The surgical field needs revamping. Some preconceived ideas must be changed. The streptococcus cannot be got rid of as long as people are concentrated in big cities and the water is polluted. In spite of chlorination, cesspool water is being drunk all the time. Colon bacilli by the million are in it. It doesn't kill people because they have become acclimated. The fellow who comes in from the rural districts to the city and changes his occupation and his method of living has a lowered resistance and becomes a potential subject for diseases which he was not subject to before—intestinal disturbance and upper right quadrant disease—because the liver takes care of most of his infectious areas, and it has the highest percentage of circulation. In other words, one lives in one's liver.

DR. JOHN B. DEAVER, Philadelphia: Just one word about T-tube drainage. The mucous membranes are very tolerant to rubber. The retention catheter, for example. I had one patient who wore a retention catheter for fourteen years, and he remained perfectly well. If the urethra is tolerant to a rubber tube, why not the common duct? Some of my patients wear the T-tube indefinitely with equal tolerance. One woman wore a tube for four years. Then I had a great deal of trouble getting her to let me take it out, because three operations done previously were followed by recurrences, and she did not want another recurrence of symptoms.

Vision Which Belongs to the Pioneer.—In another quarter, moreover, and in one which is of vital, although of less immediate concern to the layman, the need of specialists is even greater. This is the field of medical research. Our knowledge of disease has advanced so far that further progress will probably be slow, and little is to be expected except as the result of prolonged and concentrated labor. The nuggets lying on the surface have been picked up and the hidden gold will be found only by him who digs deeply and whose training has taught him where to dig. Here is needed not only the specialist, but the specialist with that unusual gift of vision which belongs to the pioneer and which urges him beyond our present confines —Peabody, F. W.: Doctor and Patient, New York, Macmillan Company, 1930.

DIAGNOSIS AND PROGNOSIS IN PEDIATRICS *

JOHN LOVETT MORSE, M.D.
BOSTON

I am going to take up the subjects of diagnosis and prognosis in pediatrics from the point of view of the practicing physician, not of the hospital. The object of the practicing physician is to arrive at the correct diagnosis with the least possible expenditure of his own time and energy and with the least possible inconvenience and expense to the patient. The hospital has to consider also the training of interns and students, the amassing of statistics and the acquisition of new knowledge, while time and expense are not as important.

DIAGNOSIS

In a large proportion of the children seen in private practice it is evident from the history, provided it is taken carefully, what the trouble is or, at any rate, where to look for it on physical examination. Observation of the parents and child during the taking of the history often shows, incidentally, that the trouble is psychologic rather than physical. The physical examination almost always makes the diagnosis plain, provided, again, it is a complete and thorough one. A physical examination is not complete, of course, or worthy of the name unless the child is stripped and examined from head to foot. After taking the history and making the physical examination the physician should know what the trouble is, that it is one of two or three things, or that he has no idea what it is. The last diagnosis is, moreover, a thoroughly satisfactory one, provided it is arrived at after proper consideration.

If the diagnosis is evident, it is unnecessary to carry out any laboratory procedures unless, for some reason, it seems advisable to corroborate it. If the diagnosis lies between a few diseases, only those laboratory procedures should be done which will aid directly in the diagnosis between these diseases. These must be done. It is as bad practice and as unscientific to carry out others which do not apply directly as it is to omit those that do. If the physician has no idea what the matter is, he should not flounder around trying all sorts of laboratory procedures and taking roentgenograms of the whole body in the hope that he may get hold of something, but should call for help.

Differential Diagnosis.—In making the diagnosis between diseases, it must be remembered that it is only differences in symptoms and physical signs which help. Symptoms and signs which are common to the diseases in question are of no assistance. Cough and dulness on percussion over the lower part of the chest are, for example, of no value in the diagnosis between solidification of the lung and fluid in the pleural cavity, while the position of the heart is of the utmost importance, being normal in one and displaced in the other. The leukocyte count, again, is of no value in the diagnosis between two diseases in both of which it is increased or diminished. It is very valuable, however, when it is increased in one and diminished in the other.

Another thing to be remembered in differential diagnosis is that, on the chances, the child has the most common of the diseases under consideration. The more uncommon the disease is, the more improbable it is that the child has it. He may have it, but it is unlikely. The burden of proof is to show that he has it, not that he has not.

---

* Read before the Section on Diseases of Children at the Eighty-First Annual Session of the American Medical Association, Detroit, June 27, 1930.

Another point to be kept in mind is that a child seldom has more than one thing the matter with it at a time. When the symptoms and signs apparently cannot be due to a single disease and its complications, it is almost certain that they are misinterpreted and that they can be fitted together, if better understood. A diagnosis of more than one disease is almost always wrong.

Diagnostic Ability.—I have been interested for many years in the difference in diagnostic ability of physicians and the explanation for it. The diagnostic ability of physicians who are poorly trained or do not take careful histories and make thorough physical examinations is, of course, a negligible quantity and not worthy of consideration. I am speaking of those who are well trained and who are reasonably careful and thorough. A physician's general medical knowledge is, of course, of great importance. The more he knows, the more likely he is to recognize a disease when he sees it. Important as knowledge is, my experience has been that, as a rule, mistakes in diagnosis are usually due not to a lack of knowledge but to lack of care, the lack of care being due to hurry or laziness. Experience is valuable in the same way as general medical knowledge. It is easier to recognize what one has seen before, perhaps many times, than what one meets for the first time. It must not be forgotten, however, that experience not infrequently means simply making the same mistake over and over.

It seems to me that the great difference between physicians is not so much in their knowledge and experience as in their ability, with given data, to separate the chaff from the wheat, to distinguish between important and unimportant symptoms and signs, and to recognize the salient points. This ability is inborn. It can, however, be cultivated to a certain extent. It is the same ability which makes a man successful in other lines—the law, business, banking. If he does not have it, he is led astray by the unimportant, and, once on the wrong track, remains on it and fails to recognize the most obvious signs and signals.

Object in Diagnosis.—The object aimed at in diagnosis is not simply to give a name to the trouble which a child has but to understand just what is wrong with him in order to treat him properly. The diagnosis should include a definite conception not only of the pathologic changes in the individual instance but also of the deviations from the normal physiologic processes caused by them. Treatment, to be rational, must be based on these conceptions and on what is known of the etiology, not on a name.

PROGNOSIS

The most important thing from the point of view of the family is the prognosis. Relatively, it cares little what is the matter with the child. It wants to know whether he will get well or not and, either way, how long he will be sick. Incidentally, whether the child lives or dies, it wants him to be made as comfortable as possible and to have the illness cost as little as possible.

Two things must always be borne in mind in prognosis in early life. First, children are sick many times but die only once. Second, the tendency to recover in early life is greater than in later life. Physicians are naturally and temperamentally either optimists or pessimists as regards prognosis. Whichever they are, they have to be constantly on their guard against this tendency. I am an optimist and always have to allow for it. The patients of certain physicians are always very sick. The question arises as to whether their pessimism is not intentional rather than temperamental. However that may be, it certainly increases the number of visits which they make. A practical point in this connection, which should not be allowed, nevertheless, to influence the prognosis, is that parents are never really angry if a child recovers after a bad prognosis, while they often are if it dies after a good one.

Prognostic Ability.—The prognosis depends on a knowledge of the usual course of the disease, the severity of the disease in the individual instance and the resistance of the individual patient. The ability to appreciate the severity of the disease in the given instance and the resistance of the given patient and, therefore, the ability to make a correct prognosis can be acquired only by experience. Some men learn more than others, however, from experience. As already stated, experience may consist merely in making the same mistake over and over. The same sort of ability is required in prognosis as in diagnosis; namely, the faculty of being able to pick out the important from the unimportant symptoms and signs, and to recognize the salient points. Mistakes in prognosis are most often made by relying too much on single symptoms or laboratory observations and not paying enough attention to the general condition and appearance of the child. For example, a high temperature or low white count in pneumonia in early life does not justify a bad prognosis if the general condition and appearance are good.

Grave Prognosis.—It is always difficult to know what course to take when the diagnosis is in doubt but the probabilities are serious, or when the prognosis appears grave or bad. Should the physician carry the anxiety himself for a time and spare the family, or should he make the family share it with him from the beginning? There may be some question as to the best course to pursue when the patient is an adult, but not when it is a child. The family should always be told. If, in acute disease, it is not told and the child dies, it always blames the physician for not telling. If the disease is a chronic one or the child is abnormal in some way, for example, feebleminded, the family is sure, in the course of time, to consult some one else who will tell the truth. It then almost never gives the physician any credit for sparing its feelings but concludes that he was ignorant and did not know what the trouble was.

In this connection, however, I must make one last observation which may be considered either encouraging or discouraging, according to the way in which one looks at it. If the family has confidence in its physician and the child dies, it is "an act of God," no matter whether the diagnosis was right or wrong, the treatment good or bad, or what the prognosis. If the family does not have confidence in its physician, the death is due to his negligence, no matter whether his diagnosis, treatment and prognosis were absolutely correct.

319 Longwood Avenue.

ABSTRACT OF DISCUSSION

DR. EUGENE ROSAMOND, Memphis, Tenn.: After listening to Dr. Morse I feel like a man who might be called on to discuss the epigrams of Epictetus. As usual he has told us the greatest number of truths in the fewest possible words. I am glad he told us that at times an acknowledgment of our ignorance of the condition of the patient should constitute a satisfactory diagnosis. A man might write a book on diagnosis and say less. I am glad he told us that common diseases are usually the correct diagnosis. I find that in consultation work the average young physician is much more apt to hunt for the symptoms of rare and unusual conditions, to hunt on Main Street for bears rather than for sparrows. We are too often prone to depend on one particular thing that we have learned, one particular symptom. I remember that several years ago I made quite a little local reputation for myself because I learned that pneumonia in childhood did not hurt, and because I had learned that when a child coughed and showed signs of pain he usually had an earache. I received a long distance call to come to see a doctor's baby. A district medical society was meeting in his town. He told me he could find nothing in the child's chest, but he had a cough and cried when he coughed. I suggested earache. An ear, nose and throat man was called and confirmed it, and I didn't have to make the night trip. I found myself afterward depending a great deal on this one particular symptom. Dr. Morse has cautioned against paying too much attention to one particular symptom.

OCCLUSIONS OF THE LUMEN OF THE FALLOPIAN TUBE*

RAYMOND E. WATKINS, M.D.
AND
FRANK R. MENNE, M.D.
PORTLAND, ORE.

The physiology and pathology of the lumen of the fallopian tube have been studied in various ways both clinically and in the laboratory. The insufflation test of Rubin has been valuable in demonstrating the patency or nonpatency of the tubal lumen. The injection through the uterus of opaque substances, especially iodized oil, has given limited visual information of both the normal and the pathologic state of the oviducts. It is possible to tell fairly accurately by the iodized oil test where the beginning of obstruction occurs.

The extent of this obstructing lesion, however, has been left to the pathologist to determine. Owing to the laborious task of making serial sections, the nature of the tubal occlusion is seldom accurately ascertained. Our interest in this subject was aroused by observing the progress of patients with pelvic inflammatory disease under conservative management. Such patients who had had definite pathologic changes in the pelvis, in the form of inflammatory masses, were seen to make steady improvement, often with disappearance of all palpable pathologic conditions in a short time. That recovery occurs in numbers of these cases is sufficiently proved by the fact that many patients become clinically well and a few become pregnant later.

These observations led us to the present study. We started this work last year, using materials from several of our hospitals and autopsy clinics. The specimens were studied while fresh and were not put in formaldehyde until after they were injected and photographed. The objects of our investigation were to find (1) the most frequent sites of occlusion of the lumen, (2) the extent of the occlusion, and (3) the microscopic appearance of sections of the involved area, in the hope of finding some evidence of resolution that might help us in determining the best clinical course to pursue in dealing with such a condition.

Hermstein and Neustad [1] and later Geist and Goldberger [2] studied the intramural portion of the tube in its relation to sterility. They used extirpated organs injected through the uterus with opaque substances, but only in those cases in which the tubes were patent. These authors concluded that variations in the course of the intramural portion offer a bar to impregnation, making the passage of sperm or ova impossible, and that such obstructions may be present with or without the closure of the fimbria.

Our study included not only patent tubes but also those with varying degrees of occlusion. In specimens in which the lumens were found by uterine injection to be closed, the tubes were injected from the fimbriated ends. In this way we were able to determine the exact extent of the obstruction. The injection of the lumens of the tubes, from the uterine or tubal ends, is bound to open or spread adherent mucous folds, so allowance was made for this in the interpretation of the pathologic changes. At first we did not attempt to measure the pressure used in injecting these specimens, and as a result we overdistended the endometrial cavity as well as the lumens of the tubes, producing overdilatation, or the injection of blood vessels. In order to control such irregularities, injections were subsequently made with measured pressure and the results were more satisfactory. The uterine and tubal cavities were filled by using pressures of 100, 150, 200 and 250 mm. of mercury. The lowest pressure required to give clear pictures was used. Bismuth mixtures and sodium iodide solutions were employed. The latter gave the best photographic results but were hard to handle because of leakage from different parts of the specimen. The bismuth injection was found to be better for demonstrating diverticula connecting with the lumens, as the bismuth could be seen in the stained

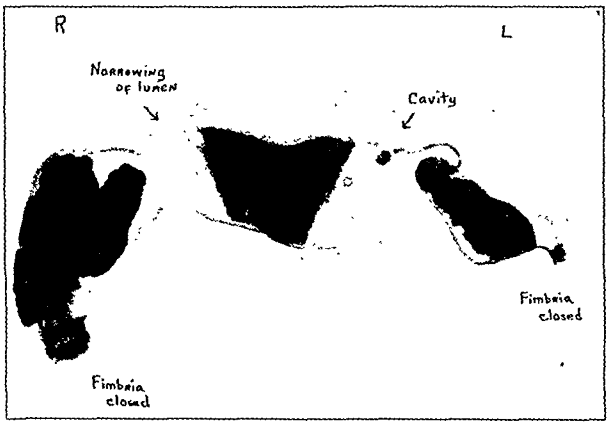

Fig. 1 (case 7).—Appearance of injected specimen in chronic salpingitis. Smears were positive for gonococci. There had been no previous attacks of salpingitis. The present attack started forty-seven days before operation. At left is seen constriction of lumen of intramural portion, with cavity at junction with isthmian portion, dilated ampulla and closed fimbria; at right, narrowing of lumen through the intramural and isthmian portions with widely dilated ampullar portion and closed fimbria.

microscopic sections. The specimens were prepared as follows: The cervix was tied or clamped, as were also the fimbriated extremities unless they were closed by inflammatory processes. Injection was made through a needle inserted into the endometrial cavity. In the event that the occlusion of either tube, in its intramural or isthmian portion, was present, one or both tubes were injected by inserting the needle distal to the obstruction. A similar procedure was used for tubes removed by the so-called Bell-Beuttner method. The fimbriated end of the fallopian tube, even when apparently closed, would seldom stand a pressure of 100 mm. without leakage.

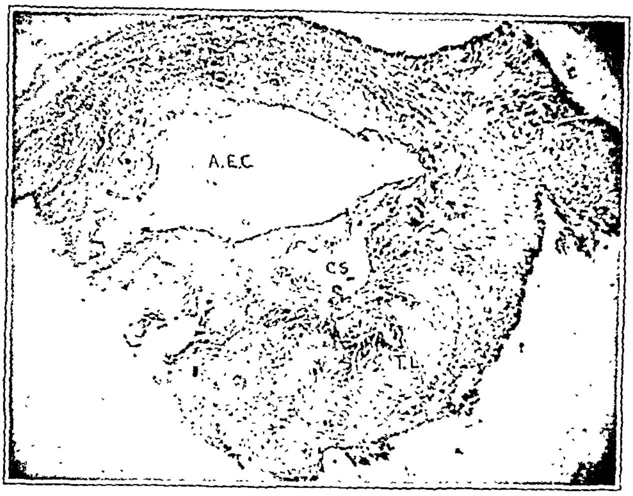

Fig. 2 (case 7).—Section through cavity adjoining the lumen in the intramural portion of the left tube illustrating: *T L*, tubal lumen; *C S*, communicating sinus; *A E C*, large epithelial-lined cavity.

The study included the following types of cases: four that were normal, twenty-six instances of chronic salpingitis, five of fibroids in the uterus, one of adenomyoma of the uterus, and one of carcinoma of the cervix.

The course of the intramural portion of the normal lumen was found to be upward and outward to the point where it joined the isthmian part. It then extended outward in quite a straight line to join the ampullar portion, where a few gentle convolutions occurred. The convolutions seen in normal specimens removed from the body were not fixed convolutions; that is, they could be made or changed at will. Geist and Goldberger[2] however, stated that in 60 per cent of their cases the course of the intramural portion was not a simple direct one but tortuous, either traversing the uterine wall in a series of gentle convolutions up to four in number or in a course marked by one or two decided angulations. They concluded that such variations in the course of the intramural portion of normal tubes may offer a bar to impregnation. The importance of these convolutions is contrary to our observations. We injected a fresh specimen within a half hour after death, before rigor mortis had set in. Numerous convolutions were seen in the intramural and isthmian portions. In the same specimen, by making gentle outward tension on the round ligaments, nearly all these convolutions disappeared. We therefore do not feel that a study of these convolutions in the normal postoperative or postmortem specimens shows the true condition in the living organ. Rubin[3] has shown and pointed out that the average course in the living is nearly always straight outward.

GROSS EXAMINATION

The following observations were made in cases of chronic salpingitis: The specimens showed varying degrees of inflammatory reaction. Adhesions were present in practically all instances. In most cases the inflammatory masses were bound down to the broad ligaments or adjacent structures. Such adhesions produced varying degrees of fixed convolutions, especially in the ampullar portions of the tubes. The uterus likewise was affected by these adhesions. It was frequently held in an abnormal position. The adhesions in the gonorrheal type were filmy and easily broken up, conforming to the observations of Curtis.[4] Different types of pathologic changes in the tubes were found, pyosalpinx, hydrosalpinx, chronic inflammatory conditions that had undergone varying degrees of resolution, and, in some, complete restitution on one side with a tubo-ovarian mass on the opposite side (figs. 9 and 10). Thickening of the walls of the ampullar portion of the tube was present in the extensive lesions, particularly in pyosalpinx. The isthmian portion at times resembled a pipe stem in feeling, often with nodes present along its course. The fimbriae were found to be closed, partially closed or open. The varying degrees of closure were caused either by adherence to the ovarian surface or by serosal contraction of the fimbriated end which was free.[5]

These free extremities were often found adherent to the broad ligament or adjacent structures. In apparently closed tubes, on close inspection, minute openings were frequently found at the site of the fimbria, with portions of the fimbria protruding but not adherent to each other. In others a contraction ring caused the fimbria to be partially closed. The finding of communicating ovarian cavities with the lumens of the tubes in those cases in which the fimbriae were adherent to the ovaries was unusual. In one specimen a tubo-ovarian cyst or hydrosalpinx with a connecting follicucyst was present. It was interesting to note the general shape and size of the tubes in the presence of these inflammatory processes. In general, the right tube had more of a semilunar appearance in comparison to the straighter left one. The right tube, on the average, was also considerably larger than the left (figs. 1, 3 and 10). It was noticed, too, that a greater degree of kink-

ing in the isthmian portion occurred on the right side. It seemed to us that these variations in shape and size were due to the greater freedom of downward dislocation of the enlarged right tube, while the left was more or less supported by the sigmoid and rectum.

In studying the lumens of the tubes of injected specimens, the occlusions were found to occur in the following locations: In the intramural portion the obstruction varied from a narrowing to a complete closure. Thus, of the forty-nine tubes studied, 30 per cent showed complete closure in this portion, with 22 per cent narrowed. The appearance of a broken line was observed in some and in others a beady appearance was noted. An interesting observation in two instances was the occurrence of cavities along the course of the intramural lumen. In the specimen as shown in figure 3, bilateral cavities, 1 mm. from the beginning of the intramural portion, and 2 mm. in diameter occurred, the lumen being closed beyond to the beginning of the isthmian part. In the specimen as shown in figures 1 and 2, a cavity 3 mm. in diameter occurred in the left tube at the junction of the intramural and isthmian portions, the lumen being patent, coursing into it and from it as shown in the roentgenogram.

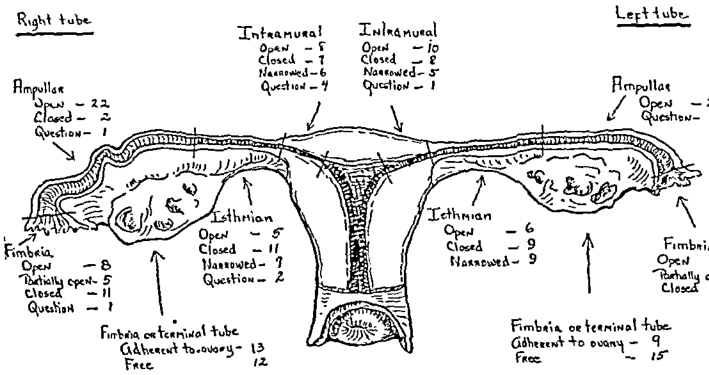

Fig. 4.—Occlusions of the lumen.

In the isthmian portion the occlusions were complete or incomplete, depending on the severity of the infection. Thus, 40 per cent were closed and 32 per cent were narrowed (fig. 4). Minute canaliculi were observed replacing the lumens in several old inflammatory cases. Dilatation of the isthmian part of the lumen was seldom observed even in the hydrosalpinx. This is probably due to its more or less fixed position within the broad ligament and the strong musculature surrounding the lumen. The course of the lumen in this region was frequently tortuous with marked fixed convolutions.

In the ampullar portion the lumen was as a rule dilated, whether the fimbriated end was open or closed (fig. 4). Chronic inflammation seemed to have been responsible for this dilatation, probably owing to distention of the lumen in the acute stage with only partial resolution having taken place at the time the specimen was studied. In only two of the forty-nine tubes studied was the ampullar portion closed, and this may have been due to failure of finding the lumen when the needle was inserted.

The fimbriated end was closed in 38 per cent of the forty-nine inflammatory tubes studied. The occlusions seemed to depend on whether the fimbriae were adherent to the ovary or not; thus, in twenty-two specimens adherent, sixteen, or 72 per cent, were closed. In twenty-seven that were free from adhesions to the ovary, only three, or 11 per cent, were completely closed (fig. 4). The extent of the occlusion varied so greatly in the different specimens that to try to arrive at an average would be of little value. In general, the occlusion varied from 1.5 cm. to 3 cm.

MICROSCOPIC EXAMINATION

The histopathologic changes of chronic salpingitis, as it affects the lumens, are influenced by many factors in addition to the normal complexity of the structure of the fallopian tubes. Malposition of the uterus, and the extent and volume of the inflammation as well as its intensity, play a rôle in the subsequent intrinsic modifications of the wall and lumens. Many interesting changes that involved the character and sizes of the lumens were revealed by microscopic sections made from blocks through the areas in the tubes where the injection materials failed to pass.

Various abnormalities were observed in *and about the intramural and isthmian portions* of the tubal channels. The lumens here presented varying degrees of narrowing but never complete obliteration. These reductions in caliber varied markedly in shape. Some were oval, others slitlike and still others had bizarre formations. Two were found with multiple openings. In general, the openings were compressed in their vertical diameters. Sloughed epithelium was often found in the form of plugs with associated wandering cells, or lying free as a result of postmortem changes or artefacts, induced by injection. In still others the epithelium showed varying degrees of hypertrophy and hyperplasia as well as regenerative changes. The mucous folds were fused at their summits and blunted or flattened out apparently according to the chronicity of the inflammatory involvement of the mucosa or perimucosal structures. In two instances in which pocket-like expansions of the lumen were observed in the gross, communicating epithelial lined sinuses were observed to lead out from the original tubal lumens to accessory epithelial lined cavities of variable size. As many as twenty scattered through the wall of the tube. from the lumen to the serosa, could be seen in a single section

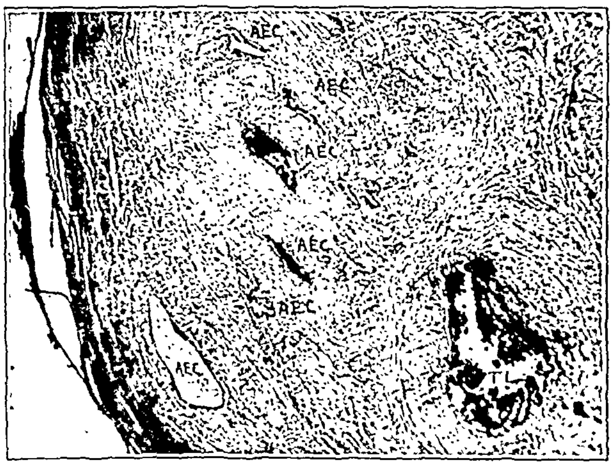

Fig. 5 (case 10).—Structure of tube with narrowing of the lumen and accessory sinuses all containing bismuth deposits: *T L*, tubal lumen; *A E C*, accessory epithelial-lined cavities.

(fig. 5). Bismuth was found to be present in these cavities (figs. 5 and 8). They often contained cores of epithelial and wandering cell débris while the inner surface was lined with a new and modified epithelium. The low cuboidal type predominated, although the tall, cilia-free columnar cells were present in a considerable number. Still others had a squamous cell morphology with evident hypertrophy and hyperplasia that indicated regeneration.

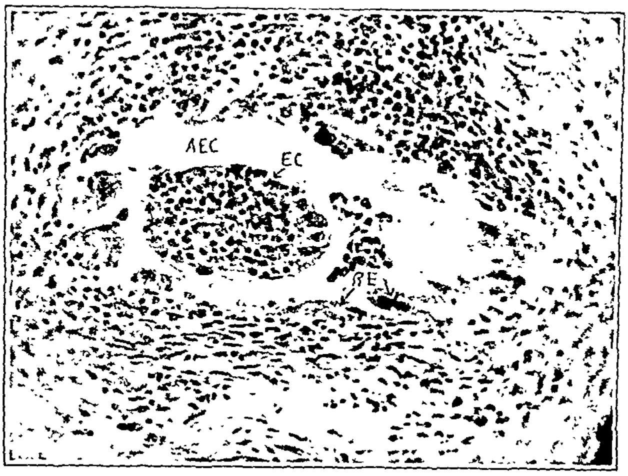

Fig. 6 (case 10).—Character of one of the epithelial-lined cavities with surrounding inflammatory reaction and repair: *A E C*, accessory epithelial-lined cavity; *E C*, epithelial-rimmed core; *R E*, regenerating epithelium around periphery.

The structures surrounding these cavities differed considerably. Some lay in massive collections of polymorphonuclear leukocytes, eosinophils, plasma cells and endothelial leukocytes that replaced the tubal wall structure or pushed it aside. Still others were enclosed in admixtures of similar wandering cells with fibroblasts and smooth muscle. In addition to these, many of the smaller ones were encircled by smooth muscle or fibrous connective tissue without wandering cell infiltration. Such instances were, as a rule, farthest away from the original lumen.

A wide range of structure was observed in the wall about the lumens. In a number of instances there was noted a diffuse hypertrophy of the musculature most marked in the circular layer. In others this was augmented by perivascular fibrosis between the muscle bundles, with here and there sparse collections of wandering cells with the eosinophilic and plasma cell types predominating. In still others the only vestiges of a preexisting inflammatory process consisted of distortion of the muscular pattern by interlacing bands of fibrous connective tissue. Such fibrosis was, in many instances, accompanied by blood vessels with all degrees of occlusions commonly seen in scar tissue. In many of these tubal walls diffuse hyalinization and atrophy associated with varying degrees of edema were noted.

Changes similar to those observed in the intramural and isthmian portions were noted in the ampullar and fimbriated divisions of the tubes. There were, however, none of the accessory epithelial lined cavities here. There was also noted a greater tendency for the processes to occupy the lumens or the perimucosal structures except in the massive inflammatory involvements when the wall was found to be compressed and less extensively infiltrated with inflammatory products. Evidence of tuberculosis was not found in any of the cases.

The constancy of the presence of certain types of wandering cells (eosinophils, plasma cells and endothelial leukocytes) in the light of the gross observations and clinical records leads us to the conclusion that the majority of the instances fall in the category of gonorrheal salpingitis. As the endometrium is the avenue by which acute gonorrheal infection proceeds to the tube, the modifications noted in the intramural and isthmian portions are of especial interest. The expansions of the tubal lumen here into small cavities or ramifying canaliculi emanate, for the most part, from dependent areas. In the isthmian region they extend down toward the broad ligament. It seems probable that mechanical factors are in part operative in determining the direction of burrowing of the infection. Our studies prove the previous suppositions as to the connection of such canaliculi and accessory epithelial lined cavities with the original lumen (injection material in the lumens, figs. 5 and 8). Such disease modifications of the lumens reveal all stages of chronicity. In only one instance were the typical abscess characteristics present (fig. 7). In all others, indications of a well developed healing were present.

A most interesting regenerative power of epithelium is to be noted in these irregularities of the tubal lumens. Aside from the minor desquamations, the epithelium seems to be intact with only partial loss of its cilia and the distortion of its pattern. The rapidity with which it extends into disease-produced cavities even when pus is still present is most remarkable. Epithelial integrity with restoration to a slightly atypical normal often occurs while the surrounding inflammation is still progressive. An indication of the regenerative power of tubal epithelium may be seen in the illustrations taken from the fallopian tubes of two dogs ten days after extensive curettement of the mucosa. This epithelial growth into infected portions of the human fallopian tube is apparently a part of nature's attempt to reestablish the lumen through these obstructed areas which occur at the site of the original lumen or in accessory sinuses produced by the spread of the infection (fig. 6). The vulnerability of the intramural portion and proximal isthmian portion is undoubtedly due to the combined factors of the normally small lumens here, the rigidity of the normal wall and the kinking at the middle of the isthmus as the infection-laden, bulky mass of the distal

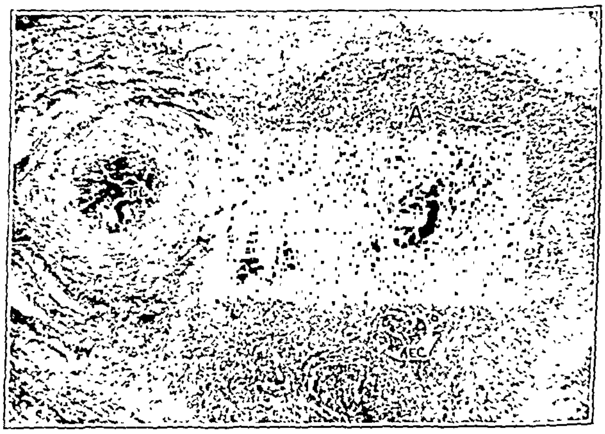

Fig. 7 (case 13).—Chronic salpingitis: Smears were positive for gonococci. *No previous attacks of salpingitis. Present attack commenced* ten days before operation. *T L*, tubal lumen; *A E C*, accessory epithelial-lined cavities; *A*, abscess formation.

portion of the tubes tends to sag into the pelvis. The latter observation is borne out by the frequent vertical flattening of the lumen in the proximal portion of the isthmus.

While the lumens of the fallopian tubes studied showed marked narrowing in the regions of the occlusion seen in the gross, the exact point of obstruction was demonstrated in a limited number of instances. Our observations in the microscopic study of the forty-nine fallopian tubes indicated that the following factors contributed to the occlusion: (1) fusion of the mucous folds by inflammatory expansion and subsequent adhesions; (2) constriction due to pressure of the inflammatory accumulations in the wall outside of the mucosa; (3) multiple inflammatory ramifications of the lumen into the wall of the tube; (4) sloughed cellular débris within the lumens, and (5) valvelike action of swollen mucous tags into the narrowings of the channel. Several or all of these factors were apparently operative in the occlusions studied. Varying degrees of reversal of the pathologic changes were observed and evidences of partial functional reconstruction were seen.

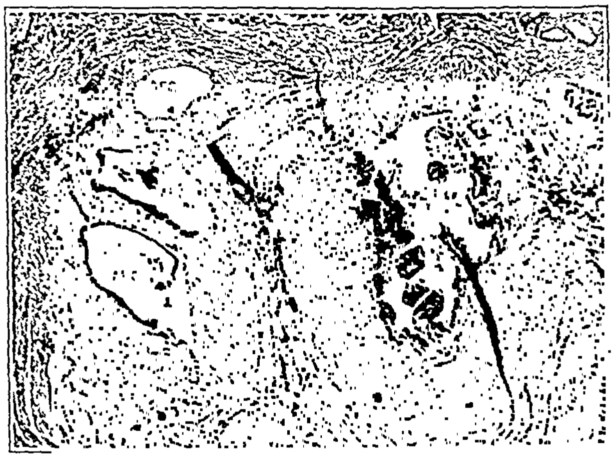

Fig. 8 (case 39).—Chronic salpingitis: Previous attack one year before; *T L*, tubal lumen; *A E C*, accessory epithelial-lined cavities.

Uterine fibroids affecting the cornu of the uterus may also cause distortion of the course of the intramural portion of the lumen producing undesirable angulations, or may encroach on its caliber causing partial or complete closure by external pressure on the tubal lumen. An adenomyoma of the right cornu involved the intramural and the proximal portion of the isthmian parts. The tubal lumen ran through the center of this growth and was occluded by external pressure. The microscopic sections of the tube showed practically no inflammatory reaction.

COMMENT

The information gained as to location, extent, character and resolution of the occlusion of the fallopian tubes in chronic salpingitis leads us to certain speculations as to their clinical rôle and amenability to conservative therapeutic management. As was pointed out in a discussion of the microscopic study, the mechanism of the occlusions differed markedly. The most difficult thing to understand was the various ramifications of epithelial-lined sinuses and cavities in the intramural and isthmian portions. In the majority of such instances studied by us, the contentions of Ries [5] and of Curtis [4] are supported; namely, that these ramifications of the lumen are outward inflammatory extensions rather than wolffian body extensions into the lumen, as is contended by Recklinghausen.[6] In some of the instances, however, the possibility of remnants of the wolffian body being the basis for the accessory epithelial-lined cavities was borne out by the fact that such channels were found without appreciable surrounding inflammation. It is difficult in such instances to establish these changes as evidence of restitution in a healed process. There can be no doubt as to the probable rôle of such irregularities of the lumen as cavities, sinuses and multiple passages in the causation of tubal pregnancy. Nor can one ignore these changes as factors in sterility. That such modifications of the tubal lumens in the intramural and isthmian portions in part determine the extent of the pathologic changes which occur distally is also evident.

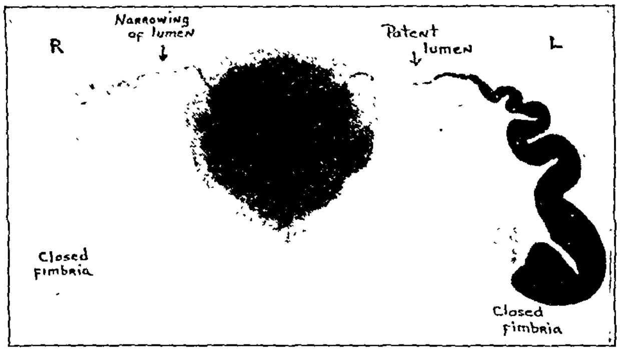

Fig. 9 (case 10).—Injected specimen in chronic bilateral salpingitis illustrating narrowing of lumen of isthmian portion of right tube. Smears were negative for gonococci. No previous history of salpingitis but pelvic symptoms began two years ago. Present attack began forty-five days previous to operation. Injection of outer portion was prevented by mutilation. Fimbria closed. Left lumen patent throughout with exception of fimbria, which is closed by adhesions to surface of ovary.

This study further demonstrated the fact that there is an active regenerative process occurring after the inflammatory condition has reached its height. As all specimens of salpingitis were in the chronic state, we believe that, if further conservative treatment had been carried out, complete resolution of the lumen might have taken place in not a few instances. That the fimbriated end has the power to resolve and become patent is shown by the fact that the fimbriae were seen in several stages of resolution. When adherent to the ovary it would seem that there is less chance for the

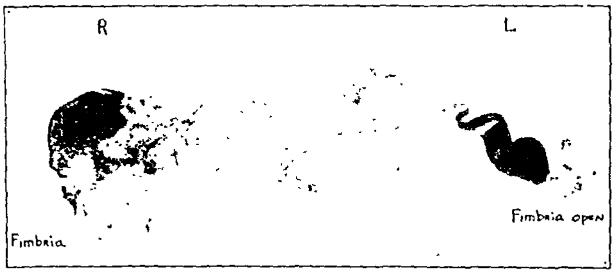

Fig. 10 (case 38).—Chronic bilateral salpingitis with adhesions plus adherent retroversion. Smears were negative for gonococci. Two previous attacks of salpingitis. Lumen of right tube obliterated except dilated ampullar portion. Two attempts at injection from tubal end were made, but lumen of isthmian region would not inject. Tube and ovary bound together in one mass. Lumen of left tube patent throughout its extent with patent fimbria. Fimbriated end was adherent to the posterior leaf of the broad ligament.

[6] Recklinghausen, F. D., and Freund, W A.: Adenomyome des Uterus, Berlin, A. Hirschwald, 1896, quoted by Ries.

recovery of patency. When free, multiple openings were frequently found at the site of the ostium with fimbriae protruding and little gross evidence of adhesions of these fimbriae to one another. In some cases in which complete resolution of the lumen had occurred, the tube was bound down by inflammatory adhesions to the posterior surface of the broad ligament and adjacent structures. The freeing of such a tube surgically would offer hope of the return of function.

Surgery directed to reestablish the lumen should not be done until an accurate diagnosis is made of the location of the obstruction. If the occlusion is at the fimbria, this may be opened by separation or by resection of a portion. The reestablishment of the lumen of the isthmian and intramural portions by our present operative methods is not satisfactory. Probing of a channel with a diameter of from 0.5 to 1 mm. is likely to produce false passages with secondary scar formation, leaving the tube in no better condition than it was before. Anastomosis of the lumen is impracticable because of its minute size. The removal of the occluded isthmian portion with the insertion of the remaining outer portion into an opening in the uterine cornu as recommended would not only leave a weakened uterine wall, but the resulting contraction of the scar in the cornu would seem to contract down and obliterate the newly formed channel. Conservative management, with the regenerative processes which follow the eradication of the infection originally causing the obstruction, seems to offer the greatest hope of reestablishment of the lumen of the isthmian and intramural portions. Insufflation or the injection of fluids through the lumen may aid in reopening the channel.

SUMMARY AND CONCLUSIONS

1. Forty-nine fallopian tubes were studied with reference to occlusions of the lumens.
2. A method of demonstrating the extent, character and resolution of the occlusions by the injection of bismuth, is presented.
3. Occlusions of the lumen may occur in any portion of the tube.
4. The most frequent site of occlusion is in the isthmian portion.
5. Resolution of the lumen depends on the absorption of the products of inflammation.
6. Healed abscess cavities and canaliculi demonstrated by bismuth injections are important causes of extra-uterine pregnancy.
7. The fimbriated end when not adherent to the ovary is frequently open or partially so.
8. In our cases, tubo-ovarian abscesses communicating with abscess cavities in the ovary were not found.
9. Operations to reestablish the lumen should never be contemplated until a definite diagnosis of the location of the obstruction is made.
10. Surgery to reestablish the lumen of the tube is not satisfactory when the occlusion is located in the intramural or isthmian portions.

Medical-Dental Building

ABSTRACT OF DISCUSSION

Dr. L. E. Burch, Nashville, Tenn.: About ten years ago, Curtis of Chicago demonstrated that gonococci could not be found in the tube after the temperature and leukocyte count had returned to normal limits, and today the authors have shown us the great regenerative power of the tubal epithelium. Both of these papers show what will happen with conservative treatment. It has happened to me in the past on more than one occasion to advise the removal of tubes and then at a later date see these patients conceive in the very tubes that I had advised removal. The tubal cavities shown by the authors are most interesting. It is also important to remember that 72 per cent of tubes were occluded that were adherent to the ovary and only 11 per cent were occluded that were not adherent to the ovary. I heartily endorse the authors' conservative views, and I should like to emphasize again the importance of conservatism in the management of pelvic inflammation. In pelvic inflammation the foci of infection in Skene's ducts, Bartholin's glands and the cervix should be eliminated and the tubes treated in a palliative way. I trust that the authors will continue their study along this line. I should like to make one suggestion, and that is that they take a like number of normal tubes, which can be procured from postmortem material or possibly from fibroid cases, and use these as controls and see whether they will throw any additional light on tubal occlusion.

Dr. Arthur H. Curtis, Chicago: The thought that physicians are going forward with conservatism in the treatment of tubal disease of gonococcal origin must be pleasing and encouraging to all. Great interest should be shown in the extension of glandular pockets into the wall of the tube, away from the lumen. I discovered, years ago, by making serial sections and longitudinal sections through the fallopian tubes after gonococcal infection, that the many glandular nests in the wall of the tube all connect with the lumen and serve as possible pockets for entrapping impregnated ova, thus predisposing to tubal pregnancy. I would urge great care in the use of iodized oil. I fear that nation-wide employment of this diagnostic aid will be followed with an aftermath of inflammatory reactions. I plan always, in infectious processes in which the disease is limited to the genitalia, to avoid iodized oil or similar solutions if I am relatively positive concerning the pathologic condition. I have known of several instances in which iodized oil was injected and operation followed rather shortly thereafter, in which the peritoneal reaction was found to be very severe. Instillation of iodized oil is a diagnostic measure of value but must be used with a great deal of caution. My experience is that operations for relief of sterility on diseased tubes are usually futile unless the fimbriated ends of the tubes can be opened. If it is only the fimbriae that are occluded and they can be teased open by blunt dissection, there is excellent prospect of relief of the sterility. But very nodular or markedly enlarged tubes are not usually amenable to surgical relief of sterility. I favor the instillation of iodized oil in those cases in which there are no palpable pathologic changes in which detailed information is required in anticipation of operative relief of sterility.

Dr. Emil Novak, Baltimore: I was interested in the illustrations of the glandlike invasion of the tubal musculature. Such pictures are not uncommon in inflamed tubes, being apparently produced by the exaggerated proliferative activity of the tubal epithelium because of the inflammation. In other cases, more particularly at the cornu, the inclusions are found to consist of what are apparently typical endometrial glands, surrounded by a mantle of what is equally typical endometrial struma. The latter picture is similar to that seen with the ordinary adenomyoma of the uterus, with which it is probably identical. I would emphasize, as Dr. Curtis has done, that, while tubal disease should be treated as conservatively as possible, the outlook for fertility in the ordinary gonorrheal type is not especially good. And this in spite of the fact that, even with isthmian inflammatory changes, a lumen still is present, as demonstrated by tubal insufflation or injection. It is perhaps true that formerly even more pessimism was felt, for it was taken for granted that isthmian inflammatory changes would practically always obliterate the lumen in that portion of the tube. It has been this consideration, indeed, which influenced many physicians from any frequent use of the operation of salpingostomy. Why open up the fimbriated end if the tube is closed near the uterus? If, however, the uterine end is often patent, as recent work indicates, there would be justification for a more frequent resort to salpingostomy in an effort to relieve sterility. One other point may be stressed, and that is the difference in prognosis as between gonorrheal and streptococcal cases. The latter are very frequent, especially in these days of criminal abortion. Those who, through error in diagnosis or otherwise, have been unfortunate enough to open the abdomen in cases of streptococcal infection of the tubes, will recall that the tubes have been large, with enormous interstitial involvement, and massive thickening of the broad ligaments (cellulitis), but with little involvement of the mucosa, and usually a patent orifice. Tubes of this type often undergo resolution, and subsequent pregnancy is common. With gonorrhea the inflammation is primarily from within, with destruction of the mucosa and early sealing of the tubes, so that the outlook, as far as fertility is concerned, is much less favorable.

Dr. Nathan Sears, Syracuse, N. Y.: Dr. Curtis mentioned a point which I think should be stressed. A few years ago I was treating a young maried woman for acute gonorrhea. In the course of time it became necessary or convenient for her to go to another city, and while there she visited another physician, who in the midst of this acute infection felt it necessary to determine the patency of her tubes. She is now sterile, is leading a very unhappy married life, and recently, in order to satisfy partially her desire for motherhood, has adopted a child. Too much emphasis cannot be placed on the care with which any of the methods are used for determining the patency of the fallopian tube in the presence of any known infection in the pelvis.

Dr. Raymond E. Watkins, Portland, Ore.: In the cases studied, we found that occlusions of the lumen occurred more frequently in all portions of the right fallopian tube; that is, there were more occlusions of the intramural, the isthmian and the fimbriated ends on the right side than in the corresponding portions of the left. This is probably of some significance, for I noticed this afternoon, in the paper on extra-uterine pregnancy, that it was stated that extra-uterine pregnancies had occurred more frequently on the right side. We interpreted the more frequent occurrence of right-sided occlusions as being due to the fact that the sigmoid probably prevented the left fallopian tube from dropping down deep into the pelvis. This may in some way be a factor in drainage or perhaps by some other means. In any event, the left tube is less frequently occluded. We also found the right inflammatory mass larger than the left in the majority of cases.

HABITUAL DISLOCATION OF THE SHOULDER

RESULTS OF TREATMENT, ESPECIALLY BY THE TENOSUSPENSION OPERATION *

MELVIN S. HENDERSON, M.D.
ROCHESTER, MINN.

Habitual dislocation of the shoulder occurs rarely, and its occurrence following ordinary traumatic luxation is not known. In 1921 and again in 1926 I[1] reported cases in which operation had been performed at the Mayo Clinic; a total of thirty patients were operated on. The present report includes further observations on the patients of this series, and on seven additional patients on whom operations have been performed since 1926.

ETIOLOGY AND PATHOLOGY

The one definite etiologic factor in the thirty-seven cases was that of primary traumatic dislocation; most of the patients attributed the dislocation to severe trauma, fall or violence. French observers insist that congenital malformation of the humeral head can generally be found, but I have not been able to substantiate this observation, and such experience has not been common in this country. General examination occasionally disclosed slight atrophy of the deltoid muscle and roentgenologic examination disclosed slight roughening or notching of the head of the bone at the upper margin which was attributed to trauma incident to the numerous dislocations. Defects in the glenoid cavity have been advanced as a cause, but proof of this by roentgenograms or by observations at operation has been lacking. It is my belief that the large majority of habitual dislocations is due to laxness of the anterior inferior portion of the capsule, but I have been unable to demonstrate this to my satisfaction in performing capsulorrhaphy. However, my conception of what the tension of the normal capsule of the shoulder should be is equally hazy, since the opportunity is seldom afforded of examining the normal shoulder capsule in the living. It is difficult to produce a dislocation by passive motion in a case of habitual anterior dislocation, even when the patient is anesthetized. I have tried to do it in a number of instances and succeeded only once. Voluntary muscular action is necessary, such as takes place when the shoulder assumes the position of forward abduction, a weak part in the capsule permitting the head to luxate. On the other hand, in cases in which posterior, "snapping" dislocation takes place, it is easily produced by passive motion.

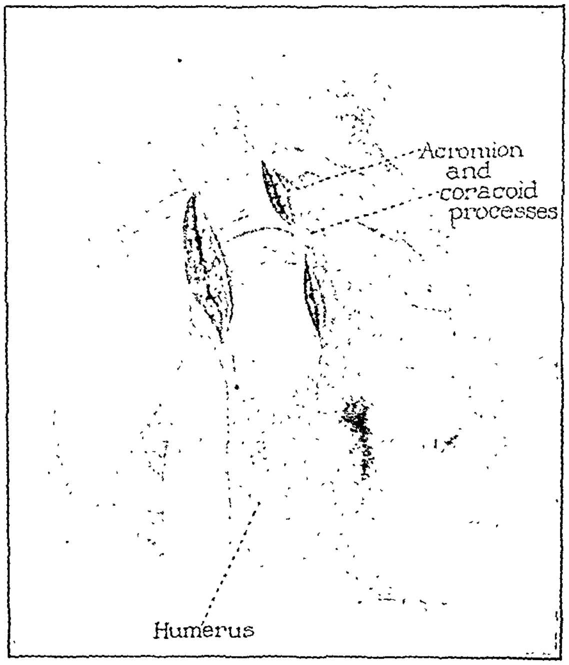

Fig. 1.—Incisions used in the shoulder.

SYMPTOMS

Usually the history given by the patient is that the primary dislocation was produced by severe trauma, and that following the reduction the arm either was not protected or it was protected for a short time only. The pain is severe and unrelieved until reduction is effected. The second dislocation may be produced by equally severe trauma, but as a rule subsequent dislocations occur without trauma or violence. The simple act of reaching forward for some object at about the level of the shoulder is the most common movement

causing dislocation. Swelling seldom follows, soreness lasts for a few days only, and pain due to involvement of the nerves does not occur. In a few of the cases dislocation was produced so easily that the patients were sometimes awakened from sound sleep by it. In one case only was primary dislocation produced without trauma, and this occurred when the patient jumped over a fence, the shoulder slipping out when he elevated his arms to balance himself. Although reductions become easier as dislocations become more frequent, a particularly difficult reduction, in which the difficulty is often due to bunglesome attempts at reduction, may be the cause of the patient consulting the surgeon for relief.

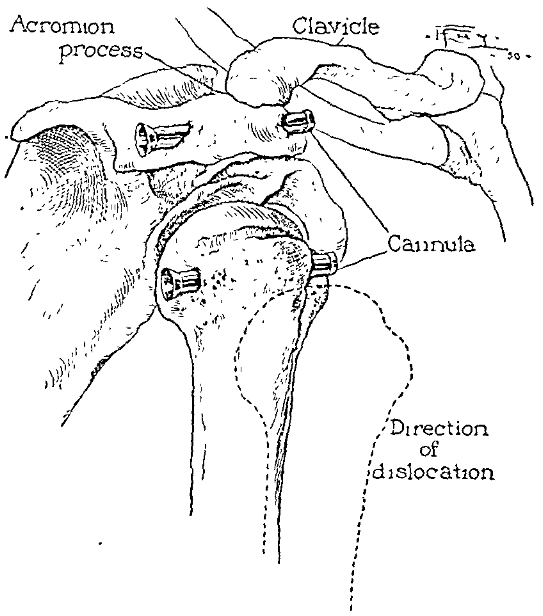

Fig. 2.—The drill holes in the acromion process and the head of the humerus; the cannulas are in place.

Tavernier [2] emphasized the importance of distinguishing clearly the habitual dislocations from the occasional recurring dislocations due to trauma which do not carry an unfavorable prognosis and which do not indicate treatment other than that of simple reduction. Until the dislocations are really habitual, surgical measures should not be urged.

Habitual dislocations are almost always of the subcoracoid type, the head resting under the coracoid process. Posterior dislocations are not common, are not so painful and may be of the snapping type. Twenty-five of the patients in the series were males and twelve were females. Twenty-nine of the patients were between the ages of 20 and 40 years. The duration of the complaint varied from six months to twenty-five years, and the number of dislocations varied from 2 to 100 or more. It can be appreciated how severely the patient's endurance has been taxed by 100 dislocations, and by the uncertainty which he feels concerning the likelihood of their occurrence.

TREATMENT

Conservative treatment is limited to the wearing of an apparatus that acts as a check to abduction and forward elevation of the arm. If nocturnal dislocations occur, and especially if epilepsy is a complication, the apparatus must be worn at night. Occasionally, shoulders which have dislocated two, three or four times will, under such a regimen, lose the habit, and the patients will not have further trouble. Too often, however, the dislocations become increasingly frequent, and it is then that surgical intervention is indicated. In some cases in which only a few dislocations have occurred the patients had a feeling of insecurity and apprehension that justified operation.

One has only to review the literature and read the descriptions of the numerous ingenious methods that have been devised for the treatment of habitual dislocation of the shoulder to realize that the results of surgical intervention have not been altogether satisfactory. Because of the rarity of the condition, it is unusual for one surgeon or one clinic to be able to base an opinion on a large series of cases; so the reports of other observers, even though the cases are few, are read with much interest. That is my reason for publishing, from time to time, data concerning results in these cases. My experience with the condition now extends over more than eighteen years.

Structurally, the shoulder joint is weak, and the bony support is practically nil. The only bony check is furnished by the acromioclavicular process which stops upward dislocation: therefore, muscular tonicity and the capsule must furnish the chief stability. The operations devised for the prevention of dislocations may be divided more or less satisfactorily and arbitrarily into five types: (1) those performed on the bony structures; (2) those performed on the capsule; (3) muscle transference and muscle lengthening; (4) check and block operations, bony or ligamentous, and (5) suspension operations.

---

[2] Tavernier, L.: The Recurrent Luxation of the Shoulder, J. Bone & Joint Surg. **12**: 458-461 (April) 1930.

Operations on the Bony Structures.—Only brief consideration need be given such radical procedures as arthrodesis and excision of the head of the bone. I excised the head in a patient who was epileptic and had suffered numerous and distressing dislocations in epileptic seizures. The head was distorted, the result of a fracture which had occurred from a roughly executed reduction. Excision through the anatomic neck relieved the patient. Hildebrand,[3] many years ago, by deepening the glenoid fossa from behind and thus making more prominent the anterior margin, aimed to prevent the head from dislocating. Eden[4] and Speed[5] accomplished the same thing by placing a bone graft along the anterior inferior margin of the glenoid fossa. They reported favorable results. I have had no experience with this type of operation, so I do not feel qualified to judge of its merit.

Operations on the Capsule.—Under this heading are included only those operations that deal with the capsule alone. Most of the dislocations are anterior, and reefing the capsule (anterior capsulorrhaphy) has been advocated for many years. Ricard,[6] in 1894, advanced this method and Thomas[7] has been an ardent exponent of the procedure. When the dislocation is posterior, posterior capsulorrhaphy is performed. Capsulorrhaphy, as will be noted, has been performed in the clinic in a considerable number of cases.

Muscle Transference and Muscle Lengthening.—Attempts have been made to utilize some of the powerful muscles or portions of them so that the muscular action will prevent dislocations. Clairmont's[8] well known operation of this type consists of dissection of the posterior fourth or fifth of the deltoid muscle, along with a portion of its insertion, lifting it upward, then tunneling through the quadrilateral space of the posterior axillary fold and fastening the muscle to the coracoid process, thus making a muscular sling for the head. In my experience, the chief criticism of this operation, aside from the necessity of two good-sized incisions and considerable dissection, has been the difficulty of getting muscle of sufficient length so that it be could be fastened readily to the coracoid process. Frequent failures caused me to abandon the operation. It should be noted, however, that if the procedure is successful the results are most satisfactory, because of the full and normal range of motion that is finally attained. I attribute the failures to the difficulties of technic and the tendency for degeneration in the distal portion of the transplanted muscle.

Heymann[9] attacked the problem by transplanting the short head of the biceps from the coracoid process, fastening it securely to the upper rim of the glenoid fossa, and sewing it to the capsule. He contended that the action of this muscle tends to reinforce the capsule and thus prevents dislocations. He mentioned six patients, all soldiers, who were cured so far as he knew; the follow-up data were not definite.

Young[10] expressed the belief that if the pectoralis major and latissimus dorsi were lengthened, the mechanics which produce dislocation would be altered. This operation is now out of favor.

Check and Block Operations.—On the supposition that a check to prevent abduction will prevent dislocation, Gallie and Le Mesurier[11] devised an operation whereby a hole is drilled anteroposteriorly through the neck of the scapula. Through this hole is threaded, from behind forward, a piece of fascia lata, knotted at the end. This is carried down and fastened through another drill hole to the under surface of the humerus, the exact site to be determined by the surgeon, who judges as to the amount of abduction to be permitted. This ligament acts as a check to abduction and thus prevents the arm from assuming the position of forward abduction in which dislocations occur. The objection that may readily be raised to this procedure is that restriction of motion is permanent.

On the premise that a block in the path of the dislocating head would stop the dislocations, a bony block was devised by Oudard[12] and elaborated on by Lenormant.[13] Briefly, their operation consists of splitting the coracoid process and elongating it so that it forms a block shaped like an elephant's trunk, against which the head impinges as it slips downward and forward in a typical subcoracoid dislocation.

Suspension Operations.—It has been logically argued that if the head can be suspended to the bony arch above and so prevented from slipping downward dislocation will not occur. This hypothesis has resulted in a number of operations, some simple and some complicated. Spitzy[14] aimed to provide suspension by the aid of an artificial ligament, namely, wrapping silk around the surgical neck of the humerus, knotting it in front, and running the long ends of the strands up and fastening them to the coracoid process, at the same time overlapping them with the capsule.

Carrell[15] described a rather complicated but ingenious operation, whereby the long head of the biceps tendon is divided and the distal end sewed to the short head. The proximal end of the divided tendon is further elongated by a strip of fascia lata which is carried posteriorly through the axilla, swung up and fastened through a drill hole to the acromion process behind. A simpler operation described by Nicola[16] appears to be sound. He divided the tendon of the long head of the biceps, drilled a hole which extended from the bicipital groove below upward to the middle of the head, and through this drill hole pulled the tendon of the long head of the biceps and fastened it to the distal end of the severed tendon at the lower end of the tunnel. He informed me that it has been used about twenty times by himself and others, with uniformly good results.

Joseph,[17] in 1917, employed fascia lata to make an extra ligament running from the head of the humerus to the acromion process. I have performed and described an operation of the same character, "tenosuspension," so called because true tendon, the peroneus longus, is used instead of fascia lata. A strong piece, half thickness to full thickness of the tendon, is placed through holes bored through the acromion process or even through the acromioclavicular articulation and the head of the humerus, providing a strong ligament that interferes with the motion of the shoulder little if any.

[17] Joseph, Eugen: Eine neue Operation zur Verhütung der habituellen Schulterverrenkung, Berl. klin. Wchnschr. **1:** 525 (May 28) 1917.

Tenosuspension was performed in twelve of the cases. Two of the operations are too recent to be reported on and therefore are excluded from consideration. The time elapsing from operation to the latest report varies from six months to six years: in one case the time since operation is six years; in one, five years; in one, four and a half years; in one, three and a half years; in one, two years; in two, one year; in two, eight months, and in one, six months. Three patients in the group were subject to epileptic seizures.

The technic of tenosuspension is simple and is facilitated by the proper instruments. I am convinced that the success of the operation depends on using a piece of strong tendon, such as the peroneus longus, and seeing to it that the ends of the tendon are sewed snug but not tight enough to cause necrosis, and that the tendon is roughened sufficiently on its smooth surface so that it will grow tight to the bony channel in which it is placed. Several failures occurred in treatment of lax acromioclavicular and sternoclavicular articulations following suture through drill holes with fascia lata, but none occurred if a piece of the peroneus longus was used. Because of these early experiences, I have never used the fascia lata in suspension operations on the shoulder, feeling that it is generally inadequate to withstand the strain. I am confident that the failures and consequent discredit to this type of suspension operation are due to the fact that fascia lata was used instead of peroneus longus or, if tendon was used, that the tendon was not well placed. I have had no experience with the operation of Nicola, but it appears to be logical and sound, and it will be interesting to note results as it comes into more common use.

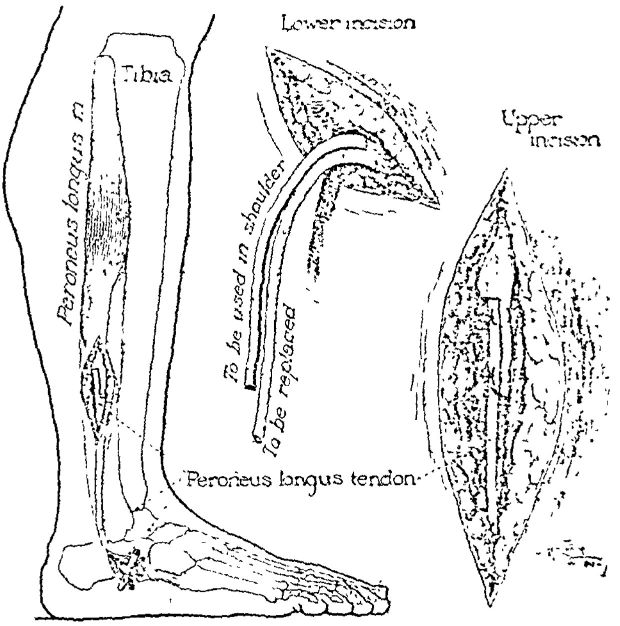

Fig. 4.—Method of removing the piece of peroneus longus tendon.

For tenosuspension, the patient is placed on the sound side between sandbags, with the affected shoulder uppermost. The skin is prepared in the ordinary manner and towels are arranged so that the head of the patient is covered; the anesthetist also is draped out of the field. The forearm and hand are wrapped in a sterile sheet, so that the arm can be moved around at will. The leg on the same side is prepared from the knee down so that incisions can be made for removal of the peroneal tendon. A tourniquet is not used on the leg.

One incision is made posteriorly, extending from the posterior aspect of the acromion process downward onto the head of the humerus. Two small incisions are made in front, one is made over the acromial area, and another over the head of the humerus (fig. 1). Parallel holes are then drilled through the acromion process or even through the acromioclavicular joint and through the head of the humerus (fig. 2). A cannula one-fourth inch in diameter is pushed through each drill hole so that the tendon will pull through easily (fig. 3).

The tendon is obtained from the peroneus longus by aid of two small incisions, one in the lower third of the leg and one over the tendon as it courses along below, and a little forward of, the external malleolus. The tendon is loosened through the upper incision and cut with a step, and with curved forceps is further loosened in its sheath and is pulled out through the lower wound. Approximately half of this tendon is then removed for the making of the autogenous ligament. The remaining portion is then pulled back upward through its sheath behind the external malleolus and the stepped ends fastened together (fig. 4). I have found that it is not necessary to use the entire thickness of the tendon as it is larger than is really necessary, and the saving of half of the tendon will offer assurance that there will be no weakness of the leg. It has been my experience, however, that removal of the entire tendon can be carried out without causing any subsequent weakness of the ankle provided the distal and proximal ends are fastened to the peroneus brevis, for the tendon of that muscle is adequate for function.

The wounds are closed, dressings are applied in the usual manner, and the arm is held to the side for approximately eight to ten days, when some movement is permitted. Abduction to a right angle is not permitted for five or six weeks. If the patient is subject to epileptic seizures, protection should be given for three or four months.

COMPARISON OF END-RESULTS FOLLOWING OPERATIVE PROCEDURES

The data presented here have been gathered in the last eighteen years (from 1912 to 1930), and comprise forty operations on thirty-seven patients (tabulation). Two types of capsulorrhaphy have been performed, the anterior and the posterior. The posterior operation is done on the posterior part of the capsule for posterior dislocations, and the anterior operation is done on the anterior part of the capsule through an anterior approach for anterior dislocations. There were sixteen anterior operations and three posterior. Six of the sixteen patients (37.5 per cent) have remained well over a period of more than ten years, the last operation having been done in 1920. Four patients report that they are better, and six report failure. Such a small percentage of success is not satisfactory. The three patients on whom posterior capsulorrhaphy was performed were cured. Eight

Clairmont operations, all more than five years ago, resulted in four cures. In this group also the percentage of success is too low. The operation described by Young was done in two cases, with failure in both. In the case in which the head of the bone was excised the result was good. Of the twelve instances in which tenosuspension has been done, ten patients are apparently relieved of all symptoms, and although some have complained of a certain limitation of abduction in the shoulder, the majority have an excellent and practically normal range of motion. As has been said, the other two operations were done too recently to justify a report. Therefore, from my experience, there seems to be little argument as to which operation is the best. Time will tell, of course, whether all patients on whom tenosuspension was performed will continue in satisfactory condition, but I believe that failures will be due to faulty technic. The technic as now practiced is simple and quickly carried out. The joint is not opened. The use of the peroneus longus muscle does not produce subsequent disability. Two of our patients were boxers and both were able, after tenosuspension operations, to participate in boxing matches, with no weakness in their legs or ankles. In case of dislocation subsequent to operation, from whatever cause, the result is listed as a failure.

Results of Forty Operations for Habitual Dislocation of the Shoulder

Operations	Cures Effected		Improvement Only,	Failure,	
	Per Cent	Number	Number	Number	Total

Tenosuspension..	100.0	10	..	..	10
Total		24	5	11	40*

* Number of patients operated on, thirty-seven.

SUMMARY

The report comprises forty operations on thirty-seven patients. Anterior capsulorrhaphy, done on sixteen patients for anterior recurring dislocation, resulted in cure in 37.5 per cent; all of these operations were done more than ten years ago. Three patients who underwent posterior capsulorrhaphy for posterior dislocation remained well. Of eight patients who underwent Clairmont operations more than five years ago, 50 per cent were cured. Tenosuspension performed on ten patients has resulted in cure in 100 per cent of cases to date; in two cases the operations have been done for more than five years; in two, for more than three years; in one, for more than two years; in two, for more than one year; in two, for more than eight months, and in one, for more than six months. The success of the operation depends on the careful placing of a strong piece of the tendon of the peroneus longus muscle to act as a suspension ligament through drill holes in the acromion process and the head of the humerus. The incisions can be kept small in size, which is a worthy consideration in women.

ABSTRACT OF DISCUSSION

Dr. Fremont A. Chandler, Chicago: Henderson's experience is unique in many respects: first, the remarkably large number of cases presenting this unusual condition; secondly, the opportunity for comparison of several types of operations for the relief of this condition, and, thirdly, the careful end-result study and analysis that he made. Anatomically the shoulder joint is dependent on its capsular and muscular structures for stability throughout its wide range of motion, with the exception of the uppermost quadrant, which is protected by the acromion process. That a point of weakness of supporting structures exists in the antero-inferior quadrant is generally recognized and accounts for the frequency of subcoracoid luxations. Recurrent dislocations in epileptic patients are usually associated with the tonic spasms of the attack and may give no history of preceding trauma to the shoulder. In the nonepileptic cases a definite history of shoulder trauma may be elicited, and the secondary dislocations are usually associated with voluntary abduction, such as throwing the arm out for a tackle in football, or raising the arm for an overhead stroke or service in tennis. In this position the head of the humerus rests against a defective fulcrum, and dislocation follows the contraction of the muscles acting on the upper end of the humerus. Impingement of the greater tuberosity on the acromion process also levers the head from the glenoid. Frequently reduction is easily effected by the patient, and as violent sport is avoided, no considerable disability is present. In other cases the dislocation may be severe and a phobia may develop, as in dislocations of the patella. The treatment by tenosuspension, if properly carried out, is not difficult, and the results are satisfactory, a ligamentous sling from the acromion process preventing pressure at the point of capsular weakness. Capsulorrhaphy in the shoulder, as in the knee and hip, is not easy to do efficiently. Transplants of portions of the deltoid through the quadrilateral space below the head of the humerus to the corocoid process are extensive procedures, and it is unreasonable to expect the muscle tissue to do other than atrophy, leaving no firm tissue to reinforce the capsule. Bone blocks at the margins of the glenoid have great merit mechanically if they are large enough to build up the anterior and inferior quadrants, a procedure not easily accomplished by most operators. The loop operations of Carrell and the ligamentum teres operation of Nicola successfully employ the principle of suspension so favorably reported by Dr. Henderson.

Dr. W. B. Carrell, Dallas, Texas: Dr. Henderson's method of suspension is on a sound mechanical basis, fairly simple in application. His results warrant its acceptance as a good operation. The use of fascia instead of tendon, as suggested, causing failure in some cases, may be further emphasized. Five years ago I had two failures in athletic men, on whom the humerus had been suspended with fascia. At the time I attributed the failure to inadequacy of the method for patients who would later follow strenuous athletic sports. On exposure of the shoulder in both cases, the fascia was intact as a fibrous cord but long enough to permit partial subluxation. With tendon, the result might have been different. To correct this recurrence, an operation was devised which seemed to have the features of a suspension combined with a reefing of the capsule. In addition, the suspension feature had more direct support by anchorage to the glenoid, looping under the neck and suspended to the acromion. The method is described in the literature, and my results in a limited number of cases have been 100 per cent in preventing dislocation and excellent as regards free motions in the shoulder. Of ten patients, four were athletes who subsequently played football, and two were epileptic. The last two had tendon instead of fascia transplant, but all have held satisfactorily. My impression now is that I prefer the Henderson operation in the average case and my own method for the athletic patient. With the enthusiasm of authorship I have convinced myself that it is not a difficult procedure, but I am convinced that the surgeon without this incentive will find Dr. Henderson's technic less difficult to follow accurately.

Dr. R. O. Ritter, Chicago: My experience with the tenosuspension operation has been very limited. I have had some experience with suspension by fascia lata, which has not been entirely satisfactory because there have been partial dislocations at various times. My experience with nine or ten Clairmont operations has been excellent in all cases except one. These have included football players and men playing professional ball. One of these patients remained intact for three years after the operation. He dislocated his shoulder at the end of that time by catching a moving street car. He was thrown violently to the ground and was picked up with a dislocation of the shoulder. Recently I have had the experience of using the long head of the biceps tendon according to Nicola, and I was impressed with the ease with which it is done. It is all executed through one incision, being done rapidly, easily and without much bleeding, which is much to be desired in an operation of this kind. The Clairmont operation is too much of an operation; there is too much exposure of tissue and too much bleeding. The fault, perhaps, with the Nicola operation is the point that Dr. Henderson mentioned. Dr. Henderson's incisions are very small, making the scar formation inconspicuous. The Nicola operation makes a rather long scar, which would be a distinct disadvantage in women. Whether this biceps tendon will stand the strain, I do not know. The one I did was done just two weeks ago. The patient was epileptic and whether the tendon will stand that strain I am not sure. The wound healed perfectly, without any reaction or swelling, and the patient says that his arm feels more secure than it did. I think, as far as the ease and rapidity with which the operation can be done is concerned, that using the long head of the biceps is very satisfactory.

Dr. Melvin S. Henderson, Rochester, Minn.: Dr. Carrell's operation is a suspension operation, but it has the additional advantage of being somewhat of a capsulorrhaphy. There seems little doubt that if the operation is properly done and the different steps are accomplished as they should be, it will relieve the condition. The only criticism, if it could be called a criticism, that I have of it is that it is rather complicated. I forgot to mention in my presentation, although it is in the text of my paper, Nicola's operation. It appears to me to be a simple and practical procedure, and I shall watch the final results with much interest. We have not tried it at the Mayo Clinic because we desired first to test thoroughly the tenosuspension operation herein described. The results that I am able to report I believe entitle the tenosuspension operation to a position well in the front rank in the somewhat large number of operations described for habitual dislocation of the shoulder. For tenosuspension, the peroneus longus should be used and not fascia lata. If the latter is used, it is not a tenosuspension. I think fascia lata is entirely inadequate and will not fulfil the duties put on it.

CHRONIC ANTERIOR UVEITIS

CLINICAL OBSERVATIONS *

M. N. BEIGELMAN, M.D.
LOS ANGELES

Chronic anterior uveitis is one of the few ocular lesions that have no standardized, uniformly accepted nomenclature. This disease, which has been in the last twenty years the subject of numerous investigations, mostly pathologic, is characterized by: (1) a slow insidious course, so that years may pass without any serious visual impairment; (2) a primary involvement of the anterior part of the uveal tract, iris and ciliary body; (3) a lack of acute inflammatory signs and symptoms, such as pericorneal congestion, pain, photophobia and lacrimation, and (4) the presence of precipitates on the posterior surface of the cornea. The lack of irritation is only relative: not infrequently the eyeball becomes congested and the patient complains of some discomfort or pain. The same is true regarding the precipitates that are found in chronic anterior uveitis in most instances, but not necessarily in every case. The fundamental and permanent characteristics, the chronicity of the process and the localization in the anterior part of the uvea are well embodied in the name accepted for the present discussion, "chronic anterior uveitis."

It is surprising how much confusion still exists in ophthalmic literature with regard to this matter of nomenclature. The "hydromeningitis"[1] of Wardrop[1] and the "aquocapsulitis" of de Wecker[2] are terms not used any more except as curiosities, but "desceinetitis" and "punctate keratitis" with and without quotation marks can be still found in modern textbooks and articles. Both these terms are entirely inadequate because they substitute a corneal condition for a uveal lesion. "Serous iritis" is another prevalent term for chronic anterior uveitis, although the ciliary body is affected in this condition as much as the iris (the same argument is valid in reference to Shieck's[3] "iritis obturans"), and the exudate in chronic anterior uveitis is not serous but distinctly cellular. For the same reasons Ball's[4] classification of the disease as a "serous cyclitis" cannot be accepted, particularly his interpretation of it as a "catarrhal inflammation of the ciliary glands." In the light of newer slit lamp investigations the term simple "cyclitis," introduced long ago by Fuchs in place of "serous iritis," is also discredited, and in his latest contribution on this subject Fuchs[5] himself speaks in favor of the term "uveitis" rather than either "iritis" or "cyclitis."

NONSPECIFIC TREATMENT OF CHRONIC ANTERIOR UVEITIS IN LATE SYPHILIS

In his monograph on "Syphilis and the Eye," Igersheimer[6] discusses the subject of chronic anterior uveitis due to syphilis in very few words, emphasizing its great rarity: ". . . whereas genuine serous iritis as a specific inflammation is very rarely observed" (während reine Iritis serosa, als specifishe Entzündung, sehr selten beobachtet wird). Although Ridley (cited by Igersheimer[6]), Mayou,[7] Urbanek[8] and others have given considerable attention to syphilis as an etiologic factor in the origin of chronic anterior uveitis, I adhered for some time to Igersheimer's opinion, and in my own work cases of chronic anterior uveitis in syphilitic patients were particularly scrutinized as to any other possible cause of the uveal lesion. However, in at least five cases of chronic anterior uveitis observed in my private practice in the last four years, a thorough examination failed to reveal any other etiology of the uveitis except the syphilitic infection. In two cases some foci of infection were found, but their removal had no effect on the course of the uveitis. In view of the wide variety of ocular lesions caused by syphilis, I felt justified in assuming that the uveitis in these cases was also syphilitic in origin. It is interesting to note that in all of them the general syphilitic infection was of long duration, from fourteen to thirty-two years. One patient presented early signs of tabes; another, those of dementia paralytica. The condition was obviously a late ocular complication in syphilis, quite different from the usual type of acute iridocyclitis in the secondary stage. The tendency to parasyphilitic manifestations observed in this small series of cases is also worth mentioning because it has a bearing on some therapeutic considerations.

In four of the five cases antisyphilitic treatment was given and, although it was conducted vigorously and for a prolonged period, no improvement could be noticed. Therefore, in two cases nonspecific therapy was resorted to with the most encouraging results:

Case 1.—D. H., a man, aged 40, contracted syphilis about twenty years before and since then had been treated systematically. Nov. 26, 1927, the condition of the left eye was as follows: visual acuity, counting fingers at 5 feet; no pericorneal congestion; precipitates on the posterior surface of the cornea; pupillary reactions sluggish; opacities in the anterior part of the vitreous.

A thorough physical examination, including tuberculin tests (Dr. Herman Sugarman), did not reveal any other pathologic change except early tabetic signs. Antisyphilitic treatment was continued for a period of more than six months. The eye was meanwhile getting worse, until the patient lost projection of light, and a complicated cataract developed. Eight injections of a preparation of lactalbumin were then given without any general or focal reaction. It was only in April, 1928, that the tuberculin treatments were started. Shortly after that the precipitates started to disappear, the exudate in the anterior chamber rapidly absorbed, and the projection of light was restored. In January, 1930, I performed an uneventful extraction of the cataract with a resulting visual acuity of 20/100.

Case 2.—Mrs. H. M., aged 61, was referred to me on account of severe pain in the left side of the head. On examination the tension of the left eye was found to be increased. There were precipitates on the posterior surface of the cornea, some of them pigmented. The anterior chamber was very deep; the pupillary reactions were sluggish. In the vitreous a few floating opacities were found.

On general examination by Dr. H. J. Gunderson, the patient presented numerous signs of incipient dementia paralytica. The blood Wassermann reaction was suspicious, and the spinal fluid was definitely positive. No foci of infection could be detected; the tuberculin test was negative. Antisyphilitic treatment failed to relieve the eye condition. The patient was hospitalized, and typhoid vaccine was used intravenously. Within four weeks the only remains of the chronic anterior uveitis were slight corneal opacities in the part in which precipitates were adherent to Descemet's membrane for a long time.

In this case the action of typhoid vaccine was obviously nonspecific. In case 1 some further elucidation of its therapeutic aspects seems to be advisable. The success of tuberculin therapy in case 1 brings up the question whether or not the uveal lesion was of a tuberculous nature, particularly because of the prevailing opinion (Urbanek, von Hippel,[9] Gilbert[10] and others) that tuberculosis is the chief etiologic factor in chronic anterior uveitis. It must be remembered, however, that in this case the tuberculin test was negative, that no evidence of systemic tuberculosis was found, and that in the ocular lesion no clinical suggestion of tuberculosis, such as iris nodules or retinal perivasculitis, could be detected. On the other hand, it was known to ophthalmologists long before the theory of nonspecific protein therapy came into existence that, in some typical syphilitic cases of parenchymatous keratitis, tuberculin was more effective than mercury or iodides. That one nonspecific agent, lactalbumin, failed to produce any reaction, while the use of the other one, tuberculin, resulted in a complete cure, is a fact worthy of serious consideration. In a previous communication I[11] emphasized the fact that at the present state of our knowledge the use of nonspecific agents is no more than a clinical experiment. Neither the type of protein to be employed nor the dosage and intervals or even the mode of use is definitely established, and in no case can the effect of the nonspecific agent be foreseen. What is needed for further advancement in this field is less speculation and more facts, properly studied and critically analyzed. That is why I am omitting entirely the tempting analogy between the use of nonspecific agents in progressive paralysis and their use in ocular manifestations of late syphilis, limiting myself to the following statement: that nonspecific therapy is of distinct value in the management of chronic anterior uveitis, which is likely to occur in late syphilis more frequently than has hitherto been admitted.

RETINAL DETACHMENT IN THE COURSE OF CHRONIC ANTERIOR UVEITIS

In the terminal stage of chronic anterior uveitis the eyeball, when totally blind and painful, is often enucleated. A pathologic examination in these cases reveals frequently a more or less complete separation of the retina (Gilbert, von Hippel) which cannot be diagnosed clinically because of the opaque media: dystrophic cornea, complicated cataract and dense vitreous opacities. This type of retinal detachment does not differ in any way from the one commonly found in atrophy of the eyeball and is caused by the organization of massive exudates in the vitreous and in the retina itself. Strictly speaking, it is not to be considered as a complication of chronic anterior uveitis, since in the terminal stage of the latter condition there is a generalized severe plastic uveitis, as well as advanced degenerative change in various tissues of the eyeball.

In the available literature I found only one case of retinal detachment complicating the early course of chronic anterior uveitis—that observed and described in 1928 by Ernest Thomson.[12] As to the reports of Heine,[13] Lauber,[14] Lowenstein[15] and Schall[16] on retinal detachment caused by uveitis, it must be stated that in their cases the inflammatory process was localized in the posterior part of the uvea rather than in its anterior portion. In addition, all of them were of tuberculous origin, and Schall, who has made the most thorough investigation of this subject, reports that the primary changes have taken place in the retina itself, in the form of extensive periphlebitis.

Under these circumstances I feel justified in reporting three cases of retinal detachment diagnosed ophthalmoscopically in a comparatively early stage of chronic anterior uveitis:

Case 3.—H. M., a man, aged 29, appeared in my office, May 5, 1928, complaining of poor vision in the left eye. On examination a typical picture of chronic anterior uveitis was found in the left eye. There was little irritation; a number of precipitates were present on the posterior suface of the cornea; the pupillary reaction was sluggish, and the vitreous had many floating opacities. No changes were found in the fundus. The intra-ocular pressure was 12 mm. (Schiötz). A thorough physical examination failed to reveal any definite disorder. The tuberculin test, however, was positive and tuberculin treatments were advised. Locally, hot applications, atropine, ethylmorphine hydrochloride and subconjunctival injections of sodium chloride were administered. Within the next two months the condition of the left eye greatly improved, and the visual acuity came up from counting fingers at 2 meters to 20/100.

[16] Schall, E.: Ueber Ablatio Retinae bei Tuberculose, Arch. f. Ophth. (von Graefe's) **109:** 205, 1922.

July 7, 1928, the patient came in complaining that he had suddenly noticed an increase in the amount of floating opacities in the left eye. On examination the eye was found to be unusually soft, 6 mm. (Schiötz), the media fairly clear, and the fundus without any changes. The next day a detachment of the lower part of the retina was diagnosed. The type of detachment was serous; no retinal tear could be detected. The intra-ocular pressure was 8 mm. In the next few months the detachment gradually progressed until the perception of light was totally lost.

Case 4.—E., a man, aged 54, came to consult me from the state of Sonora, Mexico, because he was gradually losing sight in the right eye. A mild noncomplicated case of chronic anterior uveitis was diagnosed. All foci of infection had been previously eliminated without any effect on the eye; the tuberculin test was doubtful; the blood Wassermann reaction was + + +. The usual local care and vigorous antisyphilitic treatments were advised.

In four weeks the patient returned complaining that he could not see the upper part of objects in front of him. On ophthalmoscopic examination a serous detachment of the whole lower half of the right retina was found. From subsequent communications I have learned that the patient has lost the sight in this eye entirely.

Case 5.—C. H., a man, aged 28, healthy and robust, presented on examination, March 11, 1929, the picture of chronic anterior uveitis in the left eye. The sight in this eye was reduced to counting fingers at 2 feet. Both the cornea and the vitreous were sufficiently opaque to make a detailed ophthalmoscopic examination difficult. However, no gross fundus changes could be diagnosed. The patient remained under my care for only a short time. He returned in about six months with a loss of light perception in the upper half of the visual field of the right eye. It was with great difficulty that the detached retina could be detected in the opaque vitreous.

In the next few months a secondary hypertension due to complete seclusion developed.

In considering the possible mechanism of retinal detachment in these cases, the so-called primary exudation due to choroiditis might be eliminated first. As Leber[17] pointed out, this type of retinal separation is characterized by a prompt and permanent reattachment of the retina. In the three cases reported the detachment progressed from bad to worse and resulted, in all, in complete blindness.

Traction by organized exudate has been mentioned already as the causative factor of retinal detachment in the terminal stages of chronic anterior uveitis. But in the early part of this condition there is no evidence, either clinical or pathologic, that a cicatrization sufficient to displace the retina is taking place, and an assumption to the contrary is hardly justified. Turning to the facts that may help in elucidating the pathogenesis of retinal detachment in the foregoing cases, we must first consider the changes in the vitreous body. In all these cases signs of vitreous liquefaction, such as floating opacities, hypotony and deepened anterior chamber, were present. From a liquid vitreous the fluid may under certain circumstances become absorbed through direct contact with the choriocapillaris whenever a tear is formed in the retina, or possibly through the epithelial surface of the ciliary body. On another occasion, I[18] discussed the factors that might cause or facilitate this absorption. Once a sudden loss of vitreous has occurred, the rigidity of the intact sclera will not allow the eyeball to collapse, and a transudation from the choroid with a resulting retinal detachment may take place. I admit that this assumption is no more than a working hypothesis, but it seems to have a firmer foundation than any of the previously mentioned views. It is of particular interest that in case 3, in which the onset of the separation was observed step by step, a surprisingly sudden hypotony had taken place immediately before the retina became detached, as though the contents of the eyeball diminished at once.

TRANSIENT MYOPIA IN CHRONIC ANTERIOR UVEITIS

John Green[19] was the first to call attention, in 1887, to the transient myopia occurring in connection with iritis. In his own case of bilateral iritis, Green noticed in the period of convalescence that his impaired distance vision could be greatly improved by concave glasses of about — 1.75 diopters. This refractive change persisted for six weeks, while atropine was being used freely. A similar transient myopia was subsequently observed by Green in many of his patients. Strangely enough, this interesting observation, which could be easily studied in a large amount of material, failed to arouse the interest of ophthalmologists. Outside of a casual mention of "accommodative myopia" by Eversbusch[20] in 1906, nothing was done until 1922, when Sédan[21] discussed this phenomenon in detail.

In the same year Ellett[22] reported the first case in which temporary myopia preceded the onset of sympathetic ophthalmia. In 1925 Marchesani,[23] not knowing of Ellett's contribution, described two identical observations, and finally in 1929 Swab[24] gave a detailed history of a similar case.

The following is the first report on transient myopia observed as the earliest sign of chronic anterior uveitis, when no other evidence of the latter condition could be detected:

Case 6.—Miss A. S., aged 28, Negro, came to the clinic of the Eye and Ear Hospital of Los Angeles complaining that in the preceding three days she had become "nearsighted." On examination the left eye was found totally blind as the result of a severe plastic uveitis. There was a seclusion and occlusion of the pupil; organized exudate was present in the anterior chamber, and the cornea was cloudy. In the right eye the media were perfectly clear and the fundus was normal. With a —3.00— D. she had a visual acuity of 20/20. A spasm of accommodation was suspected and the patient was given atropine which, however, proved to be ineffective. A week later the aqueous was found to be somewhat cloudy, and minute deposits appeared on the posterior surface of the cornea. A typical chronic anterior uveitis developed, while the "myopic" condition of the eye gradually disappeared.

Obviously the condition in this case was a refractive change due to an increased convexity of the lens. A spasm of accommodation, admitted by some investigators, has been disputed by others because of the fact that the condition was not influenced in any way by the use of atropine. In Nicati's[25] opinion the underlying cause of "transient myopia" is a paralysis rather than a spasm of the ciliary muscle: the anterior part of the ciliary body, in which the muscle for "distance accommodation" is situated, becomes affected first, and its paretic condition results in an overaction of the antagonist—the deeper lying muscle for "near accommodation." Whether Nicati's explanation of the origin of "transient myopia" in uveitis is agreed with depends on whether or not one accepts his views on the anatomy and physiology of the ciliary muscle.

The onset of transient myopia following a uveitis can be observed without difficulty, but it is only the patient who has lost the sight in one eye, as in sympathetic ophthalmia, who will report with a refractive change preceding a uveitis. The accumulation of similar observations in the course of chronic anterior uveitis is of importance because it points toward a primary involvement of the ciliary body, with a possible subsequent spreading of the inflammatory process either through continuity or through an excretion of the causative agent (bacteria, toxins) into the intra-ocular fluids.

STRYCHNINE POISONING IN CHILDREN *

JOHN AIKMAN, M.D.
ROCHESTER, N. Y.

Strychnine is not generally considered as a cause of fatal convulsions in small children. But little is said of this form of poisoning in textbooks on pediatrics, although it occurs in infants more than in older children and adults. The two cases here reported show a number of features in common with the other cases of strychnine poisoning that occur in this country each year.

I have been chiefly interested in the number of cases, the age incidence, the manner of poisoning in children, the laws regulating the sale of strychnine, and the prophylactic measures that might be attempted to lessen the number of these tragedies that seem to occur each year.

Case 1.—A. M., a girl, aged 2 years, was brought in convulsions to my office by her mother, Dec. 8, 1928. The mother had noted at 4:30 p. m. that the child appeared "frightened by a vacuum cleaner and was unable to walk as usual." Soon the baby fell, becoming stiff and rigid. The convulsions had since been constant. At first the parents could remember nothing unusual that the child had eaten. After the child was in the hospital, they did recall that between 1 and 2 p. m. she had eaten several cathartic tablets that a physician had given to the grandfather. The tablets had been left in a drawer and the child had been found at the open drawer with tablets in her hand. The parents had not at the time considered the ingestion of a few cathartic tablets as dangerous. There was no warning on the containing envelop, nor had they been warned to keep the tablets from the child. The child was admitted to the hospital at 5:20 p. m.

She was so hypersensitive that the least manipulation aggravated the convulsions. No complete physical examination was made, as the child was under constant treatment for convulsions. There was rigidity of all muscles; the face and legs were cyanotic. No risus sardonicus was present. The pulse was 140; the respiration, 45. The legs were abducted, the toes in flexion. There was spasm of the arms and legs. The pupils were widely dilated. The convulsions were constant.

Treatment consisted of morphine, a hot bath, colonic irrigation and lavage. The condition seemed slightly better; the cyanosis and muscle spasm became less. The child became cyanotic while the tube was in the stomach, the muscles stiffened, and the child died suddenly at 6:35.

The autopsy showed hypostatic congestion of dependent parts and cyanosis. The hands were clenched, the feet inverted, the toes drawn down, and the abdomen distended. There was extensive congestion and edema of the lungs. The left ventricle and the auricles were relaxed. There was general congestion. Three pills were found partly digested in the stomach. Some edema of the meninges was present. Each sugar coated pill contained aloin, ¾ grain (0.05 Gm.); extract of nux vomica, ½ grain (0.03 Gm.), and extract of belladonna, ⅛ grain (0.008 Gm.). The number of tablets taken was not known.

Case 2.—W. C., a boy, aged 4 years, seen with Dr. John Finigan, May 4, 1929, arose before the parents in the morning. No one saw him take any tablets. About 7:15 a. m., the child was taken with convulsions and was brought to the hospital about 8. A bottle which had contained Hinckle's cascara tablets was found empty. It was estimated to have contained about ninety tablets. Each tablet contained strychnine sulphate, 1/60 grain (0.001 Gm.); aloin, ¼ grain (0.016 Gm.); podophyllum, ⅕ grain (0.013 Gm.); extract of belladonna, ⅛ grain (0.008 Gm.); cascarin, ¼ grain (0.016 Gm.), and ginger 1/16 grain (0.004 Gm.). The past history was negative. The child probably took ninety tablets containing 1½ grains (0.09 Gm.) of strychnine and 11 grains (0.7 Gm.) of extract of belladonna. This must have been between 6 and 7 o'clock. He called his mother and began to have convulsions at 7:15. The convulsions continued until 8:45 or 9, at which time they were under the control of gas and oxygen or chloroform. An anesthetist was present until 1 p. m. to keep the severe convulsions under control. The patient's temperature was 103 F.; the pulse rate was 120, and the respiration 24. The pulse later went up to 180 and the respiration to 40.

Morphine and magnesium sulphate were given. Stomach washing gave a large amount of dark brown return smelling strongly of cascara. The patient relaxed and would keep quiet for several minutes after an anesthetic. The pupils were at first widely dilated. The skin was flushed; this cleared up first. Toward the afternoon the pupils became smaller. He died suddenly at 2:40 p. m. after resting quietly for some time. The temperature at death was 109.5 F.

Medication consisted of morphine and 25 per cent magnesium sulphate, 4 cc. subcutaneously at 9 and 11:30 a. m. Magnesium sulphate was given also by mouth. Colonic irrigation gave fair results. No autopsy was obtained.

It is evident that both strychnine and belladonna poisoning was present in each case. In neither case was diarrhea found; in fact, the returns from irrigations were unsatisfactory.

Each of the children, unknown to their parents, ate sugar-coated cathartic tablets intended for adults. The parents were unaware that the tablets contained poison and had taken no special care to keep them away from their children. This is not an unusual occurrence.

INCIDENCE

The number of cases reported in medical literature does not show the incidence of strychnine poisoning in children. A physician is not likely to see a series of cases and, owing to the brief duration of the condition in fatal cases, they are not under supervision long enough for extensive examinations and reports. The accident is investigated by the coroner and the only general report is that in the daily press.

In an analysis of sixty cases of drug poisoning admitted during a six year period to the Hospital for Sick Children at Toronto, Murray[1] reports fourteen cases due to strychnine with three deaths. "One quarter of the sixty cases and nearly one-half the deaths were due to strychnine poisoning." The cases of strychnine poisoning were all due to A. B. S. & C.

pills, the usual formula of which is aloin, $\frac{1}{2}$ grain (0.03 Gm.); extract of belladonna, $\frac{1}{16}$ grain (0.004 Gm.); strychnine, $\frac{1}{120}$ grain (0.0005 Gm.), and extract of cascara sagrada, $\frac{1}{2}$ grain (0.003 Gm.). While occasional cases with recovery are reported, the incidence of the condition is best shown by mortality statistics. Unfortunately, in most states, strychnine poisoning is listed under number 177 in the international list of causes of death with strychnine under subdivision 7 (others). As a result, no records of deaths from strychnine are recorded or can be obtained and it is not possible to show causes, age incidence and other interesting details. It would seem that strychnine poisoning should be listed separately to bring out its importance as a cause of accidental deaths in children. The Bureau of Census does show the incidence of strychnine poisoning in the death registration area of the United States, but no tabulation is made of these deaths by ages nor are the circumstances of the poisoning indicated.

The registration area in 1928 covered 95.4 per cent of the total population of the United States. The number of cases of strychnine poisoning for 1926, 1927 and 1928 were 178, 179 and 189, respectively. In Rochester there were fifteen such deaths reported from 1914 to 1929. Seven were males and eight were females. Eleven were children under 5 years of age and of these six were under 2 years of age. In 1924, seventy deaths due to accidental poisoning occurred among children from 1 to 4 years of age who were insured in the Industrial Department of the Metropolitan Life Insurance Company.[2] Definite information as to the type of poison was reported in fifty-seven of the cases. Strychnine caused twenty-four deaths. Seven of these children had eaten cathartic pills and three tonics containing strychnine. "It is truly astonishing to find so many deaths from strychnine poisoning, indicating that this cause, though perhaps not the commonest type of poisoning found among children, is certainly the most important from the standpoint of fatality."

In answer to our inquiry concerning the figures for 1926, 1927 and 1928, the statistical bureau of the

TABLE 1.—*Accidental Poisonings of Children Five Years of Age and Under in New York State (Exclusive of Greater New York) During 1926, Classified Under International List 177*

Kind of Poison	Age	Statement of Cause of Death
1926		
Arsenic (rat paste)	4	Acute toxemia from arsenic poisoning accidentally drunk
Atropine	1	Atropine poisoning accidental
Belladonna	1	Poisoning from eating pills composed of aloin, belladonna and strychnine
Camphorated oil	6 mo.	Poisoning from accidental administration of camphorated oil by mouth
Caustic potash	1	Accidental poisoning by taking caustic potash
Lye	1	Lye poisoning accidentally
Lye	1	Lye poisoning
Phosphorus	3	Poisoning; swallowed a piece of fireworks; accidental
Phosphorus	3	Poisoning; swallowed a piece of fireworks; accidental
Phosphorus	2	Poisoning of phosphorus from eating nigger-chasers
Pitch	2	Poisoning by eating pitch
Soldering fluid	1	Complete obstruction of pyloric end of stomach causing starvation (drank some soldering fluid)
Strychnine	11 mo.	Strychnine poison
Strychnine	10 mo.	Strychnine poison from cathartic tablets accidentally
Strychnine	1	Convulsions due to eating a number of tablets of strychnine
Strychnine	1	Accidentally poisoned from eating strychnine tablets
Strychnine	1	Accidentally poisoned by strychnine sulphate
Strychnine	2	Took 8 or 10 tablets of strychnine by mistake
Strychnine	2	Strychnine; swallowed cathartic tablets; accidental
Strychnine	2	Probably strychnine poisoning; accidental
Strychnine	3	Strychnine poisoning; accidental
Strychnine	1	Accidental poisoning by strychnine
Strychnine	1	Strychnine; swallowed six tablets containing strychnine poison
Strychnine	1	Strychnine poison
Strychnine	1	Poisoning; aloes and strychnine accidental
Strychnine	1	Strychnine poison accidental
Deaths of children under 5 years of age from tetanus, 5; rabies, 0		
1927		
Arsenic (rat paste)	5	Picked up package of rat poison in alley while playing
Arsenic (rat paste)	1	Eating a piece of bread with rat poison on it
Arsenic (rat paste)	4	Arsenic poisoning (rat paste) accidentally
Arsenic (rat paste)	1	Eating rat poison accidentally
Boric acid	2 days	Poisoning nursed from mother's nipple used as a wash
Horse chestnuts	3	Cholera infantum poison from eating horse chestnuts
Kerosene	1	Child drank from a can having a mixture of kerosene oil and pea juice—ptomaine
Compound solution of cresol	1	Poisoning by compound solution of cresol; accidental
Compound solution of cresol	1	Poisoning; child secured a bottle of liquid
Mercuric cyanide	1	Poisoning; mercuric cyanide eaten by a child—fireworks
Methyl salicylate	9 mo.	Methyl salicylate poisoning; accidental
Phosphorus	2	Phosphorus poisoning (rat poison); accidental
Phosphorus	2	Phosphorus poisoning (rat poison); accidental
1927—(Continued)		
Strychnine	3	Accidental strychnine poisoning
Strychnine	3	Accidental poisoning by strychnine
Strychnine	5	Accidental strychnine poison
Strychnine	1	Strychnine poison
Strychnine	3	Accidental strychnine poisoning
Strychnine	1	Probably strychnine poison (accidental); Codemene tablets
Strychnine	1	Accidental strychnine poisoning
Strychnine	3	Convulsions due to Blaud pills; strychnine poison; accidental
Strychnine	5	Accidental poisoning, strychnine
Strychnine	2	Strychnine poisoning; accidentally ate 15 Hinckle's Cascara
Strychnine	1	Accidentally ate medicine containing strychnine
Strychnine	2	Accidental strychnine poison
Strychnine	4	Accidental poisoning—pills; symptoms of strychnine
Watkin's Grippe Tablets	1	Poisoned by Watkin's Grippe Tablets; accidental
Deaths of children under 5 years of age from tetanus, 5; rabies, 0		
1928		
Arsenic (rat paste)	1	Phosphorus and arsenic poisoning; rat paste accidentally eaten
Arsenic (rat paste)	2	Phosphorus poison; rat paste
Gasoline	1	Gasoline poisoning; drank it accidentally
Kerosene	10 mo.	Kerosene drunk accidentally
Lye	2	Lye; accidental
Compound solution of cresol	1	Compound solution of cresol; accidental
Mercury (fireworks)	2	Mercury; eating Victory Snakes; fireworks
Methyl salicylate	2	Accidental overdose of methyl salicylate
Methyl salicylate	2 mo.	Methyl salicylate poisoning from oil of wintergreen to relieve colic
Morphine sulphate	10 mo.	Unknown quantity of morphine sulphate
Muriatic acid	1	Drank it at play
Phosphorus	19 mo.	Phosphorus poison
Seed of jimson weed	4	Poisoning from eating seed of jimson weed
Strychnine	2	Strychnine poisoning; Hinckle's Cascara containing strychnine
Strychnine	1	Strychnine poisoning; accidental
Strychnine	1	Strychnine poisoning; baby found bottle of nux and iron pills
Strychnine	2	Strychnine; took strychnine tablets which belonged to mother
Strychnine	4	Strychnine poison; mistake
Strychnine	1	Strychnine poisoning; child ate Blaud and strychnine tablets intended for adults
Strychnine	2	Accidental strychnine poisoning
Strychnine	3	Strychnine; took tablets by mistake
Strychnine	4	Strychnine poison; took pills for candy
Strychnine	1	Strychnine tablets; accidental
Strychnine	1	Strychnine pills taken accidentally
Strychnine	3	Strychnine poisoning; accidental
Poison (kind unknown)	3	Nature of poison unknown (sediment from maple sugar)
Poison (kind unknown)	4	Nature of poison unknown (sediment from maple sugar)
Deaths of children under 5 years of age from tetanus, 2; rabies, 0

2. Strychnine, the Most Important Cause of Fatal Poisoning Among Children One to Four Years of Age, Statistical Bulletin, Metropolitan Life Insurance Company 6: 1-2 (April) 1925.

Metropolitan Life Insurance Company[5] reported as follows: Of 726 deaths due to accidental poisoning, 273 (38 per cent) were in children under 5 years of age; 142 (nearly 20 per cent) in the second year of life. Definite information as to the kind of poisoning was obtained in 241 of the 273. Of these 82, or about one third, were due to strychnine, giving an average of 27 per year. Forty-six of the eighty-two deaths were shown to be due to cathartic or other tablets containing strychnine.

Table 2.—*Poisoning in New York State Exclusive of Greater New York*

	Accidental Poisoning (Int. List 177)		Strychnine Poisoning		
Year	All Ages	Five Years and Under	All Ages	Five Years and Under	Population
1926	107	26	14	14	5,395,133
1927	88	27	15	13	5,495,387
1928	102	27	13	12	5,595,020
	297	80	42	39	

Another valuable key regarding age incidence and cause of strychnine poisoning is given in a tabulation obtained from the Division of Vital Statistics of the New York State Department of Health,[4] showing the deaths in children aged 5 years and younger, recorded in international list 177 for New York State exclusive of Greater New York (table 1).

In 1926, 1927 and 1928 there were 297 deaths due to accidental poisoning listed under list 177 for all ages. Eighty of these occurred in children 5 years of age and under. Of these thirty-nine are recorded as due to strychnine and, as one other was listed under belladonna in A. B. & S. tablets, forty cases can be reported as due to tablets containing strychnine.

In twenty-one of these cases it is recorded that the children ate tablets accidentally and as several others "ate medicine containing strychnine" it is likely that they also were poisoned by tablets. Twenty of the forty children were under 2 years of age. The tablets indicated are cathartic or tonic prepared for adult use.

As we were unable to secure the figures for poisoning under 5 years of age for the United States, an attempt was made to estimate the number in table 3.[4] The figures thus obtained for children under 5 years of age are considerably higher than the figures obtained from the census bureau. This may indicate that this type of poisoning is more common in New York, but it does show that nearly all these deaths occurred in children 5 years of age and under.

The death rate does not show the true incidence of poisoning and the cases in which the children recover are not reported. Many children recover from strychnine poisoning. In the Toronto series[1] there were but three deaths in fourteen reported cases of strychnine poisoning; the same ratio would indicate a general average of about 850 such accidents in the United States death registration area each year. Our mortality is probably higher because many of our tablets contain more strychnine than the A. B. S. & C. reported as the cause of poisoning in all the Toronto cases.

It is not uncommon to have fatal convulsions occur and to have the cause remain unknown. Case 1 did not look unlike convulsions I have seen due to other causes. The fact that the child had eaten tablets by mistake three hours before had been forgotten. Such an occurrence could be overlooked and the interval between the swallowing of the tablets and the onset of convulsions would also help to obscure the cause. It would seem that many such cases of fatal poisoning due to strychnine must be overlooked; the deaths being attributed to unknown toxic agents. The deaths from this cause are probably much higher than the figures indicate.

Strychnine poisoning is one of the causes of serious convulsions in small children and should always be excluded in making the diagnosis. Routine chemical examination of the gastric and intestinal contents would lead to the diagnosis in obscure cases.

TABLETS

Strychnine and nux vomica have a wide use in sugar or chocolate coated cathartic and tonic tablets. From $\frac{1}{120}$ to $\frac{1}{60}$ grains (0.0005 to 0.001 Gm.) of strychnine sulphate is found in the formulas of numerous tablets of this kind manufactured for physicians. In time, the general public has become familiar with the trade names of these preparations and purchases them at the drug counter. The formula is printed on the label of the original package, but usually no special warning is given regarding the danger of taking several tablets, nor is there any suggestion that the tablets should be kept from children. The tablets are prepared for adults.

While tonic tablets and other medicines containing fairly large amounts of strychnine have become household remedies, cathartic tablets such as Hinckle's, A. B. & S. and A. B. S. & C. and others have a more general use, owing to the prevalence of general constipation. These sugar-coated tablets and many others containing strychnine are also dispensed without a warning on the drug envelop by physicians. The aggregate amount of strychnine or other poisons thus put in the hands of patients may be surprisingly large. The layman is not aware that the tablets contain large amounts of poison, and if he does notice strychnine in the formula he is unfamiliar with the toxic dosage. The package or bottle is left in reach of the small child. The brightly colored sugar or sweet chocolate coating of the tablets is not unlike candy; in fact, just such appearing candies are sold. They are swallowed without mastication, or otherwise the bitter taste of the various ingredients would serve as a sufficient safeguard. The interval required for the solution and absorption of the tablets makes detection and treatment of the poisoning more difficult. In fact, an attractive and potent poison trap is thus set for the small infant.

Table 3.—*Estimated Number of Deaths* from "Other Acute Accidental Poisonings (Gas Excepted)" (International List 177) and from Strychnine Poisoning in United States Death Registration Area*

	Accidental Poisoning (Int. List 177) Estimated		Strychnine Poisoning, Estimated		Deaths from Strychnine Poisoning Actually Reported, All Ages
Year	All Ages	5 Years and Under	All Ages	5 Years and Under	
1926	1,828	444	233	229	178
1927	1,342	473	263	228	179
1928	1,913	506	244	225	189

* Estimated by applying the percentages of the total number of deaths from all causes in New York State, exclusive of New York City, to the total number of deaths from all causes in the United States death registration area.

VALUE OF STRYCHNINE IN CATHARTIC TABLETS

The tablets most often mentioned as a cause of strychnine poisoning belong to combinations of the shotgun type. They have been so long in use by the medical profession and the public that the reason for the inclusion of some of the ingredients has been quite lost.

In an effort to get the modern view regarding the value of strychnine in cathartic tablets, letters were sent to several leading pharmacologists of this country. Opinion was about equally divided as to its value. A number were of the opinion that it had no value at all and others felt that it had some worth. Fantus [5] states that:

> Nothing may seem more logical than to add to the aloin some strychnine for the purpose of increasing the irritability of the motor neurons on which the aloin is to act; nor might it seem that anything would be more suitable to counteract the reputed tendency of aloes to produce griping than the powerful antispasmodic, belladonna. Unfortunately, by utilizing them in pill form at the same time they cannot possibly act together because of the different speed and duration of action of the three agents. Aloin is slow in action, requiring from ten to twelve hours—that is why it is generally given at bedtime. Strychnine and atropine, on the other hand, are rapidly absorbed and rapidly excreted, having but a brief duration of action. No experienced clinician would expect either of these alkaloids to act for more than four hours. By the time the aloin gets its action in, the alkaloids have long since left the system by excretion into the urine.

Fantus tested pills of aloin with and without belladonna and strychnine on thirty students and was unable to detect any essential difference. However, Yonkman's [6] experiments on dogs show that "there is a real basis for adding strychnine to pills intended to increase peristalsis, e. g., the pill of Aloin, Strychnine and Belladonna N. F."

The amount of strychnine necessary to produce sufficient action on the intestine closely approaches the toxic dose, and other cathartic tablets without strychnine and also without belladonna give very good, if not equally good results.

A more rational treatment of chronic constipation by the regulation of the diet, exercise, establishment of regular habits for bowel movements and other measures would probably give better results.

If strychnine or belladonna, both dangerous poisons, are to be used in the treatment of constipation, they should be given under the direction of a physician and probably in separate tablets or as tablet triturates. The use of strychnine in tonic tablets is more likely to have distinct value, but the added advantage of the "bitter tonic" could also be secured if these tablets were uncoated and therefore bitter. Unpleasant tasting tablets would be less likely to cause poisoning in children.

LAWS REGULATING THE SALE OF STRYCHNINE

The sale of strychnine is controlled by individual state laws rather than by federal statutes. As the United States Department of Agriculture was unable to give a digest of these regulations, it was necessary to write to each state for information. Replies were received from thirty-two states. In nearly all of these states only physicians and pharmacists can sell strychnine and it is required that a record be kept of such sales. The preparations are labeled as to composition and properties and in some states poison labels are required. These laws apply only to strychnine sold in bulk or to preparations containing amounts considered poisonous. Such laws would include strychnine tablets, $\frac{1}{3}$ grain (0.02 Gm.), but would not include strychnine in such combinations as aloin, belladonna and strychnine tablets, Hinckle's cascara, Bland compound and similar preparations.

Such tablets are exempt from restrictions because they are domestic, family or home remedies or under the somewhat vague term of proprietary remedies. Hence the practical application depends on the interpretation of these terms in the law.

The amounts of strychnine in the individual tablet is not considered poisonous. However, these tablets in bottles of 100 tablets may be sold over the counter of the drug store without a physician's prescription. In fact, the only warning is contained in the formula, which must appear on the bottle. This is usually in small type and goes unnoticed by the purchaser.

The laws controlling the sale of strychnine vary greatly in different states. The Department of Public Health of Massachusetts reports [7] that the state "Has no law prohibiting the sale of strychnine for medical purposes, and it has no law requiring proprietaries to be labeled as containing strychnine." Nevada is alone, as far as I can learn, in restricting the sale of the tablets mentioned.

In some states, dealers other than pharmacists may secure a license to sell such tablets. They may even be sold in grocery stores. While one tablet containing $\frac{1}{60}$ grain (0.001 Gm.) of strychnine would probably do no harm, the amount of strychnine contained in 100 such tablets would seem altogether too dangerous to be put in the hands of laymen. Considering the loose methods of handling poisons, it is surprising that more deaths do not occur.

PREVENTION

The loss of life from this form of poisoning is about uniform for each year. While it is not extremely high it surpasses in this state the deaths from both tetanus and rabies combined for the same age group. The deaths, mostly in small, active children, could nearly all be prevented. Most of the cases are due to the careless habit of leaving tablets within the reach of small children. Parents should be informed by publicity that such tablets can cause death. The sale and use of such compounds should be under better control.

While the elimination of strychnine from cathartic tablets would probably cause no great hardship, the suggestion that these old and time-honored formulas be abandoned would no doubt meet with active opposition from the medical profession and drug manufacturers. The latter, however, would find that the sale of other cathartic tablets would offset the loss from the combinations mentioned. Manufacturers would no doubt be glad to furnish tablets without strychnine if they were desired by the medical profession.

The formulas are now printed on the unopened bottles of strychnine tablets. The average layman does not read this formula and would be unlikely to suspect that strychnine or belladonna was present in amounts dangerous to children. The requirements of a poison label or other distinct warning would be of value if it covered a low enough range of strychnine per tablet.

[5] Fantus, Bernard: Useful Cathartics, Chicago, American Medical Association, 1927, p. 133.

[6] Yonkman, F. F.: Effect of Strychnine on the Muscular Activity of the Small Intestine in Unanesthetized Dogs, J. Pharmacol. & Exper. Therap. 37:339 (Nov.) 1929.

[7] Personal communication to the author.

Such labels may be lost while the bottle remains in the medicine cabinet. This could be prevented by having the poison warning blown in the glass. These measures would not include tablets dispensed by physicians or those obtained on prescription.

The color and flavoring on the tablets are the factors that attract the child. Sugar-coated pills or tablets containing potent drugs are all a menace to small children. If uncoated tablets were used, the bitter taste would discourage the child from eating them. This would be a simple and effective measure. The medicinal value of the tablets would not be reduced and in tonic tablets might even be increased.

Strychnine in sugar coated tablets offers a serious hazard to small children and should be better controlled by pharmacy laws.

SUMMARY

1. Strychnine poisoning is most common in children under 5 years of age, especially those between 1 and 2 years.
2. Strychnine poisoning should be listed under a separate heading in listing causes of death.
3. Strychnine poisoning is most often caused by accidentally eating medicine prepared for adults. Colored sugar coated cathartic tablets, such as Hinckle's cascara and A. B. & S., cause most of the deaths.
4. Strychnine should be considered as a cause of fatal convulsions in infants.
5. Strychnine is not necessary in cathartic tablets.
6. The use and sale of strychnine is poorly controlled by pharmacy laws.
7. If pills and tablets containing strychnine were uncoated the resulting unpleasant taste would prevent serious accidental poisoning in children.
8. Strychnine is the most serious form of accidental drug poisoning in children under 5 years of age.

THE USES AND LIMITATIONS OF SKIN TESTS IN ALLERGY *

SAMUEL M. FEINBERG, M.D.
CHICAGO

The syndromes of asthma, hay-fever, urticaria, eczema and similar conditions are no longer considered as separate clinical entities. In the light of the present conception one regards them as different manifestations of the same underlying condition. The basic pathology is the state of hypersensitiveness or allergy; and the symptoms depend on the localization of the allergic reaction. If this takes place in the bronchial tubes it is called asthma or bronchitis; if in the nose, hay-fever or hyperesthetic rhinitis; if in the skin, urticaria or eczema. It is thus apparent that there is a great tendency for this allergy or reactivity to become localized in different portions of the body.

Fortunately, it so happens that in many cases of allergy, no matter where the localized clinical symptoms occur, there is a corresponding reactivity of the skin to the same substance, as shown by the procedure of skin testing. It is hardly to be expected that the skin should be hypersensitive in every case of allergy.[1] Failure to realize this basic principle has led to many disappointments and has caused many to lose entire faith in skin tests and in the concept of allergy in general. The first skin test in the diagnosis of sensitization was performed by Blackley in 1865, using pollen in testing himself. The use of skin tests for other allergic conditions began about twenty years ago. Since that time the procedure of cutaneous testing with proteins to determine sensitization has become increasingly popular until now it has reached a point where nearly every physician is somewhat acquainted with it. As a result of this rapid spread of acquaintance with this procedure as an aid to diagnosis, many physicians and technicians have acquired a set of proteins and have begun to test patients without previous study, training or information concerning the principles involved. It is little wonder, then, that the results have been haphazard and misleading and have caused a great deal of destructive criticism in the field of allergy.

It cannot be denied that sensitization tests serve a useful purpose; neither can it be denied that they have limitations. Maytum,[2] Kern,[3] Alexander[4] and others have expressed similar views. It is my purpose in this paper to point out briefly the uses of these tests, to analyze their limitations, and to suggest possible ways of overcoming these difficulties.

Perhaps the greatest sphere of usefulness of sensitization tests is in the patients with bronchial asthma. In this group at least 50 per cent of the cases can be shown to be sensitive to substances of which most have a clinical significance. In the seasonal hay-fever cases, positive skin tests to the offending pollen may be obtained in nearly all cases; however, the majority of these offending pollens can be foretold without tests by the time of the occurrence of the symptoms and an acquaintance with the hay-fever plants in the patient's vicinity. The group of perennial hyperesthetic rhinitis cases is next in importance from the standpoint of skin testing. Approximately only one third of these can be diagnosed specifically by cutaneous tests. Eczema and urticaria, although in the majority of instances attributable to allergic causes, present great difficulty in locating the incriminating substances by skin testing. Other conditions, such as pruritus, mucous colitis, bladder disturbances, purpura, migraine and certain arthropathies, have from time to time been placed in the class of sensitization phenomena; however, in the majority of such instances the skin tests have been negative and have been of little aid.

LIMITATIONS AND DIFFICULTIES OF SKIN TESTS

The difficulties encountered in sensitization tests are attributable to many causes, which may be grouped under a few heads:

1. Skin tests may be negative to substances to which the patient is clinically sensitive.

This is perhaps the most common obstacle in diagnosis and is based on a variety of causes. The first essential in allergy work is to assure oneself that one is using active and potent materials for the tests. It is of paramount importance to know that the materials are capable of eliciting positive responses in the skin. This necessitates repeated trials of materials on patients in whom the causes of sensitization have been previously established.

[4] Alexander, H. L.: Overemphasis on Skin Tests in Allergy, Tristate M. J. 1:85 (Feb.) 1929.

In many patients there will be found refractive or negative phases in skin sensitiveness. In the same individuals, repetition of the tests at other times may give definitely positive reactions.

An inherent lack of reactivity of the skin accounts for many negative reactions. This may be due to trophic changes caused by age and other degenerations but is more commonly due to an entire lack of localization of allergy in the skin although other parts of the body may be capable of allergic response.

Another common cause for such negative reactions is undoubtedly the fact that the protein extracts used for skin testing may be entirely different chemically from the proteins with which the sensitized organ comes in contact. For example, the powdered extract of strawberry protein used for making skin tests is probably not the same as the digested, absorbed and circulating strawberry allergen causing the urticaria. This fault is probably especially frequent in the case of foods.

In young and unruly children and in cases in which the skin is practically covered with eczematous lesions, cutaneous tests may be practically impossible.

2. *Skin tests may be positive to substances to which the patient is clinically negative.*

Here again the test materials may be at fault. Frequently some extracts contain materials capable of producing nonspecific reactions. This is particularly apt to occur in the case of fish proteins. Such extracts will give reactions in almost every one who is tested. Occasionally the patient's skin is so sensitive to slight mechanical or chemical irritation that positive reactions will occur with all tests.

Although a positive skin test may represent a true sensitization phenomenon it does not necessarily signify that the substance is the actual cause of the symptoms in question. Frequently the patient has more than one allergic manifestation: his chief complaint may be bronchial asthma, but a further inquiry may elicit a history of urticaria and gastro-intestinal disturbances. It would be difficult, indeed, to ascertain under such circumstances whether a certain food showing positive reactions is the cause of the asthma or the other less important allergic symptoms.

Frequently numerous positive reactions are obtained in an individual, but perhaps only one or two are the actual cause of the clinical symptoms. Sensitization to the other substances is present but the degree of clinical exposure may not be sufficient to produce symptoms. This phenomenon may also occur in individuals who apparently present no allergic symptoms of any kind. Such reactions are to be looked on as potential causes of clinical allergy: they may at any time arouse clinical manifestations provided the allergic balance of the individual is disturbed, either by immunologic changes or by excessive contact with the sensitizing substance.

3. *Negative skin tests frequently indicate an absence of allergy.*

It is perfectly possible that some of the conditions that are now considered allergic, such as bronchial asthma and urticaria, may in some instances be caused by pathologic changes other than sensitization. Such cases would, of course, be evidenced by negative skin tests. The importance of the recognition of this principle is based on the experience that many of these instances can be successfully treated by means other than allergic.

In addition to this difficulty there may be a question of diagnostic error. For example, the symptoms of bronchial asthma may be simulated to some degree by fibroid phthisis, aortic disease, cardiac asthma and other cardiac dyspneas, a foreign body in the bronchi and pneumothorax. Naturally, sensitization tests would be of no avail in such instances.

4. *Many variations exist in the relation of the skin tests to the clinical condition.*

The intensity of skin reactions does not indicate the intensity or likelihood of the presence of clinical symptoms. Strong reactions may be no more significant than weak reactions. A weak or borderline reaction may be extremely significant. Vaughan[5] analyzed the diagnostic and therapeutic results of two series of cases, one with strongly positive reactions and the other with borderline reactions. He found the results in the treatment of the latter based on the diagnosis by the skin tests practically as good as in the former group.

At times, positive reactions are delayed for two or three hours or even twenty-four hours. Such reactions as a rule have a different appearance than the immediate reactions, but they are nevertheless of clinical importance. This delayed reactivity is more apt to occur with food tests than with any other kind of tests.

Multiple reactions are common. It is important to realize that many of these multiple reactions are merely due to group reactors. For example, an individual sensitive to the timothy pollen will usually react also to the pollens of other grasses. In addition to these group reactions there may also occur sensitization to unrelated substances, of course.

The reactions to the allergens may be of secondary or no importance. Other factors of a nonspecific nature, as pointed out by Vaughan,[6] may be of more direct significance. Although clinical sensitization may exist, other complications such as infection, mechanical difficulties and neurogenic factors may be of still greater importance. To illustrate, bronchial asthma originally due to feather sensitivity may be complicated by bronchial infection. The source of sensitization may have been subsequently removed or have been obviated by an increased tolerance of the individual. However, the complicating bacterial infection may prolong the asthmatic symptoms. It is necessary to study the disease and the patient as a whole and not merely focus one's attention on the skin tests.

To correlate the results of skin tests with the cause of the allergic symptoms, considerable technical information is necessary. *A positive skin test is a clue that should stimulate a search to locate the article it represents. For this purpose it is essential to have a detailed knowledge of the composition of household articles, foods and other materials.*

HOW DIFFICULTIES ARE TO BE MET

The limitations enumerated in the process of cutaneous testing may be combated in a number of ways, depending somewhat on the particular difficulty in question. The procedures to be considered in such instances may be classified as follows:

1. *Other Methods of Tests.*—When cutaneous tests have repeatedly failed to produce positive reactions, it is still possible to elicit them by other means. The most common of these is the intracutaneous injection of liquid extracts. While such a procedure is in my opinion unsafe for routine use, it is quite safe if tests are done only with materials that have previously given a nega-

[6] Vaughan, W. T.: Rôle of Specific and Nonspecific Factors in Allergy and Allergic Equilibrium, J. Lab. & Clin. Med. **13**: 633 (April) 1928.

tive cutaneous test. This method with fair frequency will give positive reactions of clinical significance when the cutaneous method has failed. It must not be forgotten, however, that the intracutaneous method, as shown by Peshkin [7] and others, is productive also of frequent false positive reactions and must therefore be interpreted with extreme caution.

Quite frequently the skin will show no reactivity but the mucous membranes, especially of the conjunctiva and nose, will be quite sensitive. In such cases the conjunctival or intranasal tests are available. These tests are particularly applicable to atypical pollen cases. A solution of the pollen or a speck of dry pollen is placed in the conjunctival sac or in the nose. The allergic reaction manifests itself in the eye by marked vascular injection, swelling of the mucosa, lacrimation and itching. In the nose, rhinitis, sneezing, injection and swelling of mucous membrane with nasal obstruction constitute a positive reaction. This test may also be used with some of the other allergens.

In some cases in which the allergic manifestations are localized in the bronchi the skin, conjunctivae and nasal mucosae may be entirely nonreactive. In such instances it may be possible to elicit positive response by blowing some of the material into the patient's respiratory tract or allowing him to inhale the emanation in question. A positive reaction will consist either of a definite spasmodic cough or of an attack of bronchial asthma. This method is practical only with the inhalant materials.

Ingestion of natural foods as a means of testing will be described more fully under another heading. It has been shown by Kahn [8] and others that occasionally a subcutaneous injection of the test protein will produce a positive response when the cutaneous and intracutaneous routes have failed. Another method that has been discussed in recent years is the procedure of passive transfer. This is based on the principle that the intradermal injection of a small amount of serum from an allergic individual into a normal skin sensitizes the latter to whatever substances the former was sensitive. Although this method of indirect skin testing is not practical in many cases, it nevertheless may offer a solution in those instances in which direct testing is impossible.

2. *Clinical Corroboration and Therapeutic Trials.*—It is hardly possible to overemphasize the fact that sensitization tests are merely laboratory guides that point the way for further investigation. Clinical corroboration is the final test. To be of value, positive skin tests must correspond with the clinical facts, such as time of the appearance of symptoms and exposure to allergens. In all cases in which the laboratory tests are positive, their relation to the clinical symptoms must be proved by trial. This means, for example, to have the patient stay for a short time around horses in the case of positive skin tests to horse dander, or to eat a certain article of food in the case of a positive reaction to that food. A prompt response with the production of clinical symptoms corroborates the diagnosis of the etiology.

The foregoing procedure presupposes that the patient has intervals of freedom from symptoms. In those instances in which the symptoms are constant and also in the cases in which multiple positive tests are obtained, it is necessary first to attempt to free the patient from his clinical manifestations before exposure experiments are tried. All the materials represented by the positive skin tests are eliminated at once and then exposure, by inhalation or ingestion, is tried with one thing at a time. Thus it is usually found that only a portion of the positive tests are clinically significant.

In the event that sensitization tests are all negative or that the management based on the positive tests has not yielded expected results, it is still possible that the individual is clinically sensitive to the substances that have given negative tests. It is particularly in such instances that the methods of systematic elimination and addition should be tried. In general, two methods are available: systematic elimination of one or more articles at a time from the diet or home environment, or the complete elimination of all substances likely to cause sensitization and then the gradual addition of one or two of these articles at a time. In the case of foods, this means the elimination primarily of such foods as are the most common causes of sensitization, such as egg, wheat, milk, peas, beans and chocolate. In the case of inhalant sensitization it means the removal from the patient's environment of such things as dogs, cats, horses, feathers, hair in furniture or other articles, cotton dust and other sources of dust.

3. *Investigation of Other Factors Than Allergy.*—The most experienced of the allergists are ready to admit that other factors than allergy may play a part in the causation of symptoms ordinarily attributed to sensitization. In addition to that, diagnostic errors are possible because of the similarity in symptomatology of allergic disease and other conditions. It is only by a thorough investigation of the patient that these conditions can be discovered. This should include a detailed history with especial attention to certain differential points; a complete physical examination especially to exclude complications of the allergic disease or to diagnose conditions that may be mistaken for it; laboratory examination, particularly a Wassermann test, eosinophil count of the blood, sputum examination and urinalysis. In respiratory cases it should include also a roentgenogram of the chest and nasal sinuses. Occasionally, chemical examination of the blood or the determination of the basal metabolic rate may be of value. Above all, there should be a willingness on the part of the clinician to consider other possible causes than allergy for the particular symptoms.

It is evident, then, that a complete, comprehensive clinical experience with the allergic diseases and conditions resembling them is required to enable one to judge, interpret and follow up skin tests for allergy. For this purpose such an individual should be one who is skilled in the diagnosis of medical diseases and who has subsequently obtained experience in the diagnosis and management of allergic conditions. A technician cannot be relegated to the making of skin tests and reporting them to the referring physician with the necessary advice. With the availability of considerable periodic literature on allergy and the increasing number of allergy clinics, it is possible for practically every physician to gain first-hand knowledge about the allergic diseases and their investigation by sensitization tests.

SUMMARY

In recent years the use of protein skin tests in the etiologic diagnosis of allergic disease has become increasingly popular. Because of the inherent difficulties and limitations of these tests, much disappointment and criticism have resulted. Sensitization tests should be considered only as laboratory guides. There are many limitations to the value of skin tests in allergy. Negative skin tests do not necessarily mean an absence of sensitization to these substances. Positive tests do not necessarily indicate the cause of the clinical symptoms. Complicating factors may be more important than the allergy. The difficulties may be met chiefly by employing, when necessary, other methods of testing, such as intracutaneous, subcutaneous, conjunctival, nasal and passive transfer; by clinical trials and elimination diets; by a broad knowledge of the clinical correlation and clinical experience in allergy; and by a willingness on the part of the clinician to consider other causes than allergy.

ABSTRACT OF DISCUSSION

Dr. Edward Mansur, Jefferson City, Mo.: I should like to ask whether, in the case of feather asthma, especially canary feather, the likelihood would be equally positive for sparrow feathers, the two birds being quite similar in many characteristics. I should also like to ask whether there is any feather allergy desensitization treatment available that is worth while and whether the ketogenic diet has been tried and is of any value, particularly in the treatment of allergic asthma.

Dr. S. M. Feinberg, Chicago: On the question of the relation of canary feathers and sparrow feathers, I must admit that I haven't paid any attention to sparrows, although I have had experience with canary feather sensitization. It is very rarely the case that a single canary will cause trouble in a patient who has a canary in his home. It is a matter of exposure to a much more massive dose. For instance, in the clinic I have a patient who is sensitive to canary feathers, who has asthma and who is exposed to approximately seventy-odd canaries by reason of the fact that his brother, with whom he lives, breeds the canaries. I haven't investigated or thought about investigating the question of sparrow feathers. I imagine, judging from experience with other related feathers or foods, that there would be a relationship, as shown by skin tests and probably as shown by clinical symptoms. I rarely use the feather treatment. It is much more simple to eliminate feathers in the home, to substitute other materials for pillows and covers, or merely to enclose the pillows in an impermeable, dustproof, rubberized sheeting. Occasionally, I have treated feather cases, but the results are not as successful as one is led to believe from the literature. As to the ketogenic diet, I have not experimented with that. I know of some experiments that are going on in New York on that. Apparently from what I hear some results are being obtained in bronchial asthma. Of course, a ketogenic diet means a marked reduction in certain starches. I know that many patients who have asthma and other sensitizations are sensitive to certain foods, particularly the cereals, and it seems to me not at all impossible that some of the results with the ketogenic diets are due to elimination of certain foods.

Dr. A. H. Sanford, Rochester, Minn.: I have seen a close relationship between chicken feathers and goose feathers in testing, and in the practical application I think that the patient often does not know whether he is using goose or chicken feather pillows. One patient, particularly, was sensitive to chicken feathers, to the protein of chicken meat and egg albumin, and yet the only thing he really actually was sensitive to was the chicken feathers. Unfortunately, he was in the poultry business and could not handle the chickens very well.

Dr. Edward Mansur, Jefferson City, Mo.: I have a patient with feather asthma. I tested with all the feather dust tests I could lay hands on but none were sparrow feathers. The patient reacted far more markedly to the canary feather allergy than any other. I asked her if she had canaries at home. She said she did not. I said, "How about sparrows or any other kinds of birds?" She said, "I did notice this spring when the boys cleared out my back porch and got rid of the sparrows' nest I got better." The sparrows built a nest in the porch. When that was eliminated, she noticed considerable improvement.

Clinical Notes, Suggestions and New Instruments

THE TREATMENT OF PANCREATIC FISTULA FOLLOWING RUPTURE OF PANCREAS: REPORT OF A CASE

William K. Fast, M.D., Atchison, Kan.

The statement is made by Stern[1] that traumatic pancreatitis, in which the pancreas is the only organ originally injured, is an exceedingly rare condition. The full and comprehensive review of the literature, as given by that author, is ample support to that statement. Whenever pancreatic fistula has developed following injury, the management of these cases has been perplexing and the mortality always high.

The management of one of these rare and interesting cases, wherein the pancreas was the only organ injured and in which healing was complete three weeks after the appearance of the fistula, is herewith described. The treatment used in this case was first suggested by Potter[2] for duodenal fistula. I have been unable to find that this treatment has been used in the treatment of pancreatic fistula, prior to its use in the case reported here. Potter[3] states that he has no knowledge of the treatment being applied to a definite pancreatic fistula before. The fact that the destruction of tissue from a duodenal fistula is, per se, due to the pancreatic juice makes the treatment the same.

REPORT OF CASE

L. H., a woman, aged 20, a waitress, was admitted to the Atchison Hospital at 7 p. m., March 15, 1930, thirty minutes after being injured in an automobile collision. She was first examined by Dr. Charles W. Robinson, who found that she was unconscious and bleeding profusely from a 6 inch scalp wound. She soon reacted satisfactorily, a roentgenogram of the head was negative for fracture, and the scalp wound was then sutured. She complained of general aching and soreness and a feeling of uneasiness in the epigastrium.

Nausea and vomiting developed forty-eight hours after admission, together with extreme constipation, which was accompanied by gradual abdominal distention. There was no blood in the vomitus and none in the stool secured on the second day. After gastric lavage the nausea and vomiting subsided. Small doses of morphine were then given but nothing by mouth. On the eighth day a large bowel movement resulted from an enema, after which the distention disappeared and the patient felt much better. The pulse and temperature were normal at this time.

With relief of the distention there appeared in the left hypochondriac region an elongated swelling which bulged forward beneath the left rectus muscle and extended from the left costal margin to below the umbilicus and was moderately tender on palpation. Fluctuation was present.

Complete urinalyses at this and previous examinations were normal. The blood count was: red blood cells, 3,000,000; hemoglobin, 75 per cent; white blood cells, 8,000; polymorphonuclears, 73 per cent.

At the request of Dr. Robinson, who had made a diagnosis of localized hematoma, in which I concurred, an exploratory celiotomy was done. Following a preliminary injection of one-fourth grain (0.016 Gm.) of morphine sulphate, the skin and subcutaneous tissues were infiltrated with 0.5 per cent procaine-epinephrine solution. The abdomen was opened through a high incision in the left side of the rectus. There was no free fluid in the general peritoneal cavity and the intestines were collapsed and empty. A tag of omentum was adherent to a low right rectus scar, the site of a previous appendectomy. This was divided.

There was a tense, bluish mass completely filling the lesser peritoneal cavity. This tumor had the appearance of a hemorrhagic mass, part of which may have been due to hemorrhage but resembled the grumous fluid so often seen in the lesser peritoneal cavity accompanying hemorrhagic pancreatitis. After the general peritoneal cavity had been isolated by packing, an opening was made in the gastrocolic omentum. This released 2.5 liters of thin, dark, bloody fluid which was odorless and contained flakes of fibrin and many strings of necrotic fat. With the absence of a bleeding or injured vessel on the posterior stomach wall and the release of thin, blood-tinged pancreatic fluid containing strings of necrotic fat, the diagnosis of rupture of the pancreas was certain.

[2] Potter, Caryl: *The Treatment of Duodenal Fistula*, J. A. M. A. 88: 899-901 (March 19) 1927.

[3] Potter, Caryl: Personal communication to the author.

Deeply situated and opposite the first lumbar vertebra there was a small necrotic mass of fibrous and fatty tissue which on removal was followed by the discharge of 2 drachms (8 cc.) of clear fluid. The prevertebral portion of the pancreas had been crushed against the anterior surface of the body of the vertebra, producing a V-shaped defect in the upper edge. Because of the extreme friability of the pancreatic tissues, suturing was abandoned after one attempt.

A one-half inch rubber tube was placed in the defect and another of like size placed as low as possible in the lesser peritoneal space. Both were brought out through the opening in the gastrocolic omentum, which was then closed tightly with interrupted sutures of catgut. Both tubes were fastened in the lower end of the incision, which was then closed in the usual manner.

The patient felt better immediately, and during the first forty-eight hours drainage was profuse and blood-tinged. After forty-eight hours it lessened, a change of dressings being necessary only four times each twenty-four hours. On the fourth day it was clear and watery, and at this time the first evidence of skin irritation appeared. On the fifth day the lower tube was removed. The clear fluid discharging from the remaining tube was alkaline in reaction and the amount in twenty-four hours was 4 ounces (120 cc.). The wound and surrounding area were kept thickly covered with zinc oxide paste and the remaining tube was removed on the tenth day. The patient had been placed on a high fat, antidiabetic diet which showed no influence on the amount of secretion being discharged. I then found that a high carbohydrate diet in the form of Karo syrup given in 2 ounce (60 cc.) doses every four hours would reduce the amount of secretion to 2 ounces in each twenty-four hours, but this did not lessen the digestion of the wound, which was pronounced within forty-eight hours after the removal of the upper tube. A raw, crater-like area surrounded the tube site and in twelve hours increased three-fourths inch in diameter.

I decided to try the treatment suggested by Potter[4] as being of value in duodenal fistula, together with the modification suggested by Warshaw and Hoffman.[5] A number 12 french catheter was inserted as far as possible into the fistula and the wound packed with gauze saturated with a 10 per cent aqueous solution of Witte's peptone. Tenth normal hydrochloric acid was instilled into the catheter at the rate of twenty drops an hour. The high carbohydrate diet was maintained.

Twenty-four hours after the institution of this treatment, digestion of the wound ceased, the crater began to fill in, and it was entirely closed fourteen days later. The catheter in the meanwhile was shortened 1 inch a day, after the tenth day. From the fourteenth to the twenty-first day the granulating wound was kept covered with beef extract paste.

Thirty days after operation the patient was discharged from the hospital with the incision entirely healed. Though the patient had been on a high carbohydrate diet and at the same time losing much of her pancreatic secretion, I was unable at any time to find sugar in the urine. On the day on which she was discharged her weight was 11 pounds (5 Kg.) under her weight on admission.

A recent report from the patient states that she is well, has regained her normal weight, and is attending to her usual duties.

Western Union Building.

FIXATION AND SUPPORT OF THE HEAD IN FRACTURES OF THE CERVICAL VERTEBRAE

Louis Le Fevre, M.D., and Samuel Jackson, M.D.
Muskegon, Mich.

Our method of fixation of the fragments and support of the head in fractures of the cervical vertebrae is submitted to the profession for trial and criticism, in the belief that it will, in the hands of others, as it has in our hands, prove more satisfactory to both the surgeon and the patient than existing methods in common use.

The device consists of two pieces of wrought iron bent into ovals, the one to fit the body curve around the neck under the chin, the other to fit around the neck and over the shoulders, the latter oval being slightly larger than the former. The two ovals of iron are placed with their long axes at right angles to each other and are held together by screws on which turnbuckles are placed, which permits of raising or lowering the upper oval, laterally, anteriorly or posteriorly. The two ovals are broken in front and behind and hinged at one of these places so as to permit of opening and closing them around the neck.

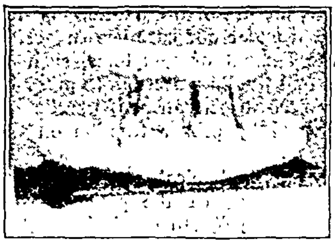

Fig. 1.—Front view of apparatus for fixation and support of the head in fractures of the cervical vertebrae.

The two iron ovals are padded heavily with felt and covered with clean gauze. The device is then ready to be placed about the neck of the patient, which is done by opening it on the hinge mentioned, and closing it when it encircles the neck. When properly in position, the lower oval rests on the shoulder girdle and conforms to the contour of the shoulders, and there is a space of about an inch all around between it and the base of the neck. The upper oval fits snugly, but not uncomfortably, just under the chin and under the occiput. Traction can then be exerted on the head by screwing the turnbuckles so as to raise the upper oval and the head with it, the weight being transmitted to the shoulder girdle through the turnbuckles and the lower oval. One or more turnbuckles can be turned more than the others, and in each case that we have treated we have found that anesthesia and numbness in the extremities due to pressure on the nerve roots rapidly disappear as the apparatus is adjusted. We have used the disappearance of pressure symptoms as a guide to the amount of screwing of the turnbuckles.

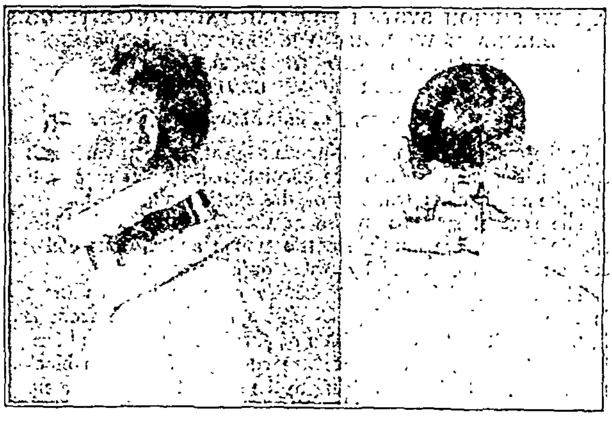

Fig. 2.—The illustration on the right shows the splint in place and the joint which is opened to admit it around the neck. On the left note the snug fit under the chin and occiput, obtained by twisting the turnbuckles between the two rings.

The advantages of this apparatus that we have noted are these:

1. Traction on the head, or the equivalent of it, the head being raised off the broken fragments of the cervical vertebrae as the screws are turned, can be closely and accurately adjusted

---

[4] Potter, Caryl: The Treatment of Duodenal and Fecal Fistula, J. A. M. A. **92**: 359-363 (Feb. 2) 1929.

[5] Warshaw, David; and Hoffman, W. J.: High Intestinal Fistula, J. A. M. A. **94**: 1050-1052 (April 5) 1930.

and can be maintained in an ambulatory patient. This permits of a much shorter period of hospitalization.

2. It is more comfortable to the patient than either a plaster cast or a halter.

In each of the four cases we have treated with this device, the numbness, anesthesia and paralysis in the extremities have been rapidly relieved, a large part of it spontaneously with the application of the apparatus. Bearing in mind that concellated bone heals much more slowly than compact bone, we have left the fixation apparatus in position in each case at least eight weeks, but during the last four weeks all patients were ambulatory, and two patients during the last two weeks resumed their regular occupations of janitor and fireman, respectively.

While the nerve filaments in the spinal cord that are destroyed or severed will never regenerate, the use of the fixation apparatus in the four cases we have had under our care has suggested to us that a surprisingly large amount of symptoms, such as anesthesia, paralysis, numbness and tingling, are due to pressure and edema, which might easily become permanent if unrelieved, but which can quickly be relieved by proper traction on the head.

Credit should be given for the mechanical construction of this apparatus to Mr. Fitzgerald, one of the patients, who suffered a fracture of the body of the fourth cervical vertebra in an automobile accident, and who was moved to exert his ability by the discomfort of lying flat on his back with traction on the head exerted through a leather halter under the chin and occiput. In recognition of this, we are inclined to christen this device the Fitzgerald collar.

An effort was made to make the lower rim of the collar conform more closely to the contour of the chest wall by using a piece of flat sheet metal hammered so as to fit. This was discarded, however, as it was never as comfortable as the more clumsy appearing ring.

Although we have used this only for fractures, it suggests itself for any condition in which it is desired to remove the weight of the head from the cervical vertebrae, as in caries of the spine from tuberculosis.

A NEW SIPHON SYSTEM FOR MAINTAINING CONTINUOUS DRAINAGE WITHOUT AIR BLOCK IN THORACIC EMPYEMAS AND IN INFECTIONS OF OTHER BODY CAVITIES

F. M. Pottenger, Jr., M.D., Monrovia, Calif.

In the maintenance of continuous aspiration from various body cavities, several obstacles are encountered. Chief among these are the mechanical features of the suction apparatus.

The several systems in use at the present time include the simple siphon, the multiple bottle siphon and various elaborate suction pumps operated by water or electricity.

The simple siphon is satisfactory only as long as the tube is free from bubbles of gas. These bubbles arise from leaks in the circuit and decomposition of purulent material and irrigating fluids. The two sources are equally effective in blocking the siphon. The bubbles rising to the highest point in the siphon break the column of fluid in the suction side with consequent loss of negative pressure. The negative pressure exerted by a siphon is equal to the height of the column on the suction side less the height of the column on the intake side.

The multiple bottle systems require great care to avoid leaks which minimize the additional suction gained by their use. Though correct in theory, their use in hospital wards has not proved satisfactory because of the constant attention required. An air leak is as effective in ruining their efficiency as is a collection of bubbles in the simple siphon.

Pumps, on the other hand, are costly to purchase, are costly to maintain and require continuous attention.

The apparatus illustrated in figure 1 is a modification of a simple siphon, so designed that all gas and air bubbles are eliminated from the circuit. *D* and *A*, standard one-liter Pyrex flasks, are placed in slots at each end of a double arm standard. *D* is filled with the irrigating solution and *A* with sterile water. *R* is a large receiver which at all times must have sufficient fluid in it to cover the end of the suction hose which connects *A* with *R*. *C* and *S* are the special rubber connections which have been described in another article.[1] To *C* the irrigating hose is connected, which may enter the cavity either separately or through a Y-tube connected with the aspiration tube 2 as shown. Tube 2 is then connected to one leg of *S* and the suction hose 3 is connected to the other leg. Each hose has its corresponding clamp.

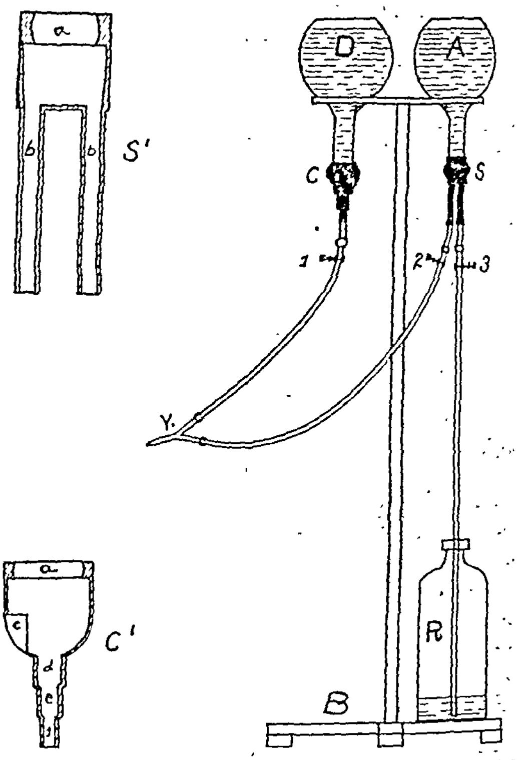

Fig. 1.—Apparatus used for chest drainage in the chest surgery service, Los Angeles County General Hospital, and cross-sections of special rubber connectors. *A*, air reservoir; *B*, two-armed standard for holding flasks; *C*, one-legged connector with valve in side wall; *C'*, same in cross-section; *a*, suction ring; *c*, valve; *d*, ⅜ inch outlet; *e*, ¼ inch outlet; *f*, ⅛ inch outlet; *D*, reservoir for irrigating solution; *R*, pus receiver; *S*, special two-legged rubber connector; *S'*, cross-section of same; *a*, suction ring; *b*, *b*, two legs; *Y*, Y-tube used to connect chest with irrigating and aspiration circuits; 1, clamp on irrigating tube of same number; 2, clamp on aspiration tube of same number; 3, clamp on suction tube of same number.

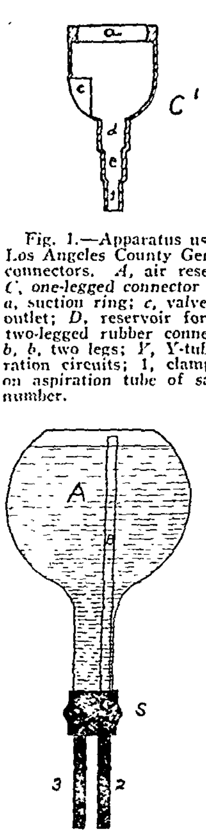

Fig. 2.—Air reservoir connected so as to prevent back flow: *A*, air receiver flask filled with water; *B*, glass tube secured into leg 2 of rubber connector and extending above the surface of fluid in *A*; *S*, special rubber connector; 2, aspirating circuit connection; 3, connector with tube to pus receiver.

This circuit operates as follows:

D, with its connection to tube 1, is a reservoir for irrigating fluid which can be used as needed. Tube 2 is the aspirating tube which removes the pus from the cavity. Tube 3 drops straight to the receiver *R*. *S*, acting as a gas separator, completes the circuit between 2 and 3 while *A* acts as a gas receiver. Any gas that may enter tube 2 has little effect on the circuit for it is removed at *S* as soon as it reaches that point, rising to the surface and displacing an equal volume of liquid. Any gas that develops in tube 3 rises to the surface of *A*, likewise displacing an equal quantity of water. In this manner a definite suction is assured at all times.

To obtain the best operating results, tube 3 should be of about three-eighths inch in diameter and of stiff noncollapsing rubber.

This circuit is so effective that, even if hose 2 is wide open, aspiration will continue as long as there is fluid in *A*. In order to study the hydrostatics of the drainage operation carefully, a manometer may be inserted at *Y*, and then one may care for one's patients more intelligently.

---

[1] Pottenger, F. M., Jr.: Rubber Flask Connectors for Hypodermoclysis, Intravenous Therapy and Other Uses, J. A. M. A. 95:1503 (Nov. 15) 1930.

This apparatus, because of its simplicity of construction and manipulation, can be used for many purposes when suction is required. If 2 is extended by a glass tube (fig. 2), the efficiency is in no way impaired and the clinician can be certain that no fluid will flow back down tube 2 from the receiver, should any accident occur. With this addition it has been used at the Los Angeles County General Hospital to aspirate pus from peritonitis cases and postoperative secretions from throats.

Because of the ease with which *A* can be refilled, it is easy for a nurse to change the flask as it becomes empty. In closed aspiration circuits, such as those used in treating empyema of the thorax, aspiration can be maintained for a period of from several days to more than a week without changing the fluid in *A*.

The rubber devices, because of their simplicity of construction, durability and ease of use, add materially to the success of this method.

This apparatus has been developed and adopted in the Chest Surgery Service of the Los Angeles County General Hospital.

STAB WOUND OF THE NECK FOLLOWED BY CEREBROSPINAL FLUID LEAKAGE AND NO SPINAL CORD INJURY

H. K. Shawan, M.D., Detroit

It is unusual for stab wounds of the neck to puncture the dura —thus causing cerebrospinal fluid leakage—without damage to the spinal cord. The patient whose history is given was seen at the Receiving Hospital, Detroit.

REPORT OF CASE

History.—T. H., a white man, American, aged 30, was admitted to the hospital, June 13, 1930, having been stabbed in the left side of the neck. He thought that a portion of the blade still remained in the wound. He stated that it was difficult for him to rotate his head without pain. At no time had he complained of numbness and tingling or sharp shooting pains in the upper extremities. His bladder and bowel control was unaltered. He could walk and had no motor dysfunction in either of the upper or lower extremities.

Physical Examination.—The patient was robust, fully conscious and well oriented. His speech was normal. His gait was unimpaired. There were no signs of spinal or cerebellar ataxia. The pupils were round and equal and reacted to light and in accommodation. Extra-ocular movements were normal. The fundi were normal. There were no signs of cranial nerve palsies. The reflexes were normal throughout. There were no pathologic changes in sensation.

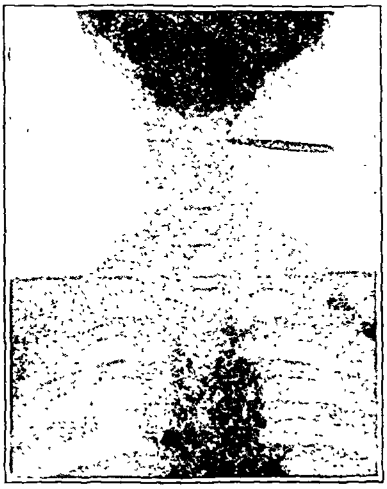

Fig. 1.—Anteroposterior view of the neck. The opaque shadow represents the knife blade, which is found piercing the vertebral column between the fifth and sixth cervical vertebral arches.

The neck was held rigid and slightly tilted to the left. He could move it in all directions, but with difficulty. A thin, blunt, hard object was felt under the skin in the middle third of the left side of the neck. The stab wound was 1 cm. in length. At examination it was noted that the dressings at the site of the lesion were wet and on watching the wound in the neck, a flow of cerebrospinal fluid was noted. This flow was not continuous but fluid trickled out every four or five minutes.

Roentgenograms of the neck showed a horizontal, long, opaque, metallic shadow, the tip of which had pierced the space between the fifth and the sixth vertebral pedicles on the left side (figs. 1 and 2).

Operation.—Under local anesthesia, a short skin-plane incision was made over the base of the retained foreign body, parallel to and just above the stab wound. It was an easy matter to remove the blade through this operative field. The broken off knife blade measured 5.5 by 1 cm. The skin incision was closed without drainage.

Postoperative Course.—His convalescence was uneventful. The cerebrospinal fluid leakage stopped immediately. There was no fever and the blood counts were normal. The patient was discharged in three days. Examination four months later showed complete recovery.

COMMENT

In the majority of stab wounds of the dura-arachnoid the spinal cord symptoms and signs are outstanding. The cord may be partially severed, it may become edematous because of injury, or some of the spinal arteries may be sectioned, with consequent subarachnoid hemorrhage.[1]

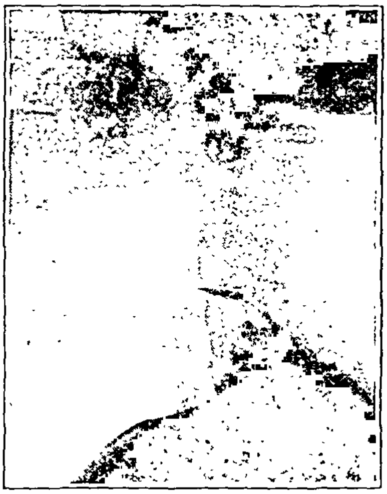

Fig. 2.—Lateral view of the neck with the knife blade in close proximity to the interpedicular space. It is suggested that the dura-arachnoid is pierced at this situation.

It is unusual to have cerebrospinal leakage without symptoms of spinal cord damage. The earliest case is probably the one described in 1743 by Cuvillier.[2] His patient walked 80 miles after a stab wound in the back. Soon a tumescence appeared which on incision showed serosanguineous fluid, presumably a mixture of blood and spinal fluid. The possibility of infection with cerebrospinal fluid leakage after stab wounds of the spinal canal is imminent. Such a case was recently reported by Mavrodin and Tzovaru.[3]

In the case reported here there was a stab wound puncturing the spinal membranes. For several days there was a leakage of cerebrospinal fluid. No early or late spinal cord interference occurred. No meningitis developed. There was a complete recovery after the extraction of the knife blade.

The Peculiar Distinction of Hippocrates.—To Hippocrates belongs the peculiar distinction that he was the first definitely to discard the idea that disease was due to the gods or other fantastic imaginings; he dissociated medicine for the first time from religion and philosophy. This alone would have been sufficient to insure his immortality, but he went further, and by crystallizing the loose knowledge of his predecessors and contemporaries into systematic science, he became the master to whom modern medicine owes the art of clinical inspection and observation. So keen were Hippocrates' power of observation, and so clear are the written descriptions ascribed to him of such diseases as tuberculosis, puerperal (childbirth) convulsions, and epilepsy that, with a few changes and additions, they might be incorporated entire in any modern textbook of medicine.—Oliver, W. W.: Stalkers of Pestilence, New York, Paul B. Hoeber, Inc., 1930.

THE ETIOLOGY OF GINGER PARALYSIS

Within the past year a peculiar form of paralysis has afflicted many persons, particularly throughout some of the Midwestern or Southwestern states. Government experts have asserted confidently that the numbers of the patients run into the thousands, thus exhibiting what may reasonably be termed epidemic proportions. Evidence has rapidly accumulated indicating that the unique malady is closely associated with the drinking of fluidextract of ginger. The latter has been sold extensively for many years, since the introduction of the Volstead Act, for beverage purposes, because of a ruling of the Prohibition Bureau to the effect that the official fluidextract of ginger is a nonpotable beverage, thus removing the restriction from its sale. The disease that has come to be designated as "ginger paralysis" could scarcely have been caused by the familiar U. S. P. fluidextract; otherwise the morbidity would have been much greater and the incidence of the paralysis far more widespread. Many of the victims freely admitted having used fluidextract of ginger for years without effects other than those attributable to its alcohol content; hence the conclusion that an adulterated and poisoned product was being circulated for sale last winter.

An investigation was undertaken by the United States Public Health Service[1] as soon as the seriousness of the situation became manifest. Many puzzling features attended the early clinical examinations. The quantity of the ginger fluid consumed was apparently not the determining factor in the seriousness of the symptoms. A single drink is known to have produced essentially the same result as that following prolonged use of the product over a period of some days. Transitory alcoholic intoxication often occurred, as might be expected; but the really untoward symptoms were delayed, usually about ten days. The victims presented bilateral wrist drop and foot drop of varying degrees of severity. The picture became that of a flaccid paralysis for the most part of the distal muscles of the lower and upper extremities, pointing to involvement of the lower motor neurons localized in the lower lumbar and lower cervical regions of the cord. The unsuspected presence of arsenic or lead and other heavy metals in the beverage was soon ruled out by careful chemical examination of samples of the offending product. Phenol compounds were found to be present.

The familiar phenols, such as carbolic acid, are prompt in their toxic action, in contrast to the delay in the paralysis produced in the ginger victims. Confusion was added by the observation that, whereas rabbits and calves responded to the dangerous fluidextracts somewhat as the human victims did, monkeys seemed to be immune. The effective investigations of Smith, Elvove and their co-workers[1] in the Public Health Service seem to have fixed responsibility for the unusual human disease on tricresyl phosphate, and more specifically on the triorthocresyl isomer. The pharmacology of this unsuspected product was not known until the present occasion for its investigation. The systemic action of ordinary cresols is prompt; that of the cresyl phosphate is slow. It is assumed by the government pharmacologists to be absorbed as such, rather than hydrolyzed in the alimentary tract of man. It is further postulated that the substance has a special selective affinity for nervous tissue, where it may be disintegrated in situ. Such behavior would explain the long latent period in the onset of the paralysis and the persistence of the toxic action.

The details of the mode of action need to be worked out further, but the complicity of the triorthocresyl phosphate can no longer be doubted. Investigation and inquiry have revealed, by way of confirmation, that an adulterated ginger prepared by addition of technical tricresyl phosphate to U. S. P. fluidextract of ginger made to approximate the composition of the suspected toxic gingers behaved like them in pharmacologic tests on susceptible animals. The precise reason for including triorthocresyl phosphate, which is now revealed as a highly specific poison, in commercial ginger extracts is not known. Smith and his colleagues regard it as reasonable to suppose that it was included there by unscrupulous producers on account of its physical or other properties that make it difficult to distinguish from the normal ginger constituents. Only a chemist of some ability, the government report adds, could have thought of this; and had there been anything known about the pharmacologic action of the substance and the possible dire consequences, it is probable that it would never have been used and the disasters would never have happened. The elucidating research illustrates what may be expected from the newly organized National Institute of Health, where the investigation of ginger paralysis has been prosecuted. Smith and

Smith, M. I.; Elvove, E., and Frazier, W. H.: The Pharmacological Action of Certain Phenol Esters, with Special Reference to the Etiology, Second Report, ibid. **45**: 2509 (Oct. 17) 1930.

Elvove have expressed a wonder whether there are not many other organic compounds of great pharmacologic interest, perhaps some with therapeutic possibilities, awaiting the attention of the pharmacologist. This question may well form the basis for part of the program of the national institute. To unscrupulous manufacturers the study of the unexpected menace attending unwarranted adulteration of foods and drugs should be a lesson of far greater impressiveness than the mere fear of convictions and fines. The producers of the noxious ginger extracts have unwittingly become potential murderers rather than merely criminal purveyors of adulterated products.

THE DEATH OF PROFESSOR EIJKMAN

The death, at the age of 72, of Dr. Christiaan Eijkman, professor of hygiene in the University of Utrecht and a Nobel prize laureate of recent years, deserves more than passing notice. He has long enjoyed the distinction of being the scientist who first produced experimentally a disease of dietary origin. His researches paved the way for the discovery of the vitamins and much of the investigation of recent times in the field of nutrition. Eijkman's pioneer studies related in particular to the long puzzling malady of the Far East known as beriberi. This disease, a peripheral neuritis resulting in paralysis, had been known from remote times. The popular belief was that it must be due primarily to an infection, though there were physicians who assumed that the disorder might be referred to faulty diet. In 1884, Admiral Takaki of the Japanese navy became converted to the idea that foods richer in protein than those commonly consumed by the sailors, who subsisted largely on rice and were prone to develop beriberi, might bring relief. He made a crucial test. A Japanese training ship with 276 men on board set out for a nine months' cruise. During this time 169 cases of beriberi developed, with 25 deaths. Soon thereafter another training ship with a similar crew started over the same route, but its diet was radically changed. The most marked departure in the regimen was to reduce the quantity of rice and include a fairly liberal supply of milk and meat. The change, a reviewer[1] writes, was nothing short of miraculous. During ten months only fourteen cases of beriberi developed, and every one of these men had refused to adopt the modified diet. Beriberi thus came to be looked on as a protein deficiency disorder.

Years later, about 1896, a chance observation by Eijkman turned attention to other possibilities. This Dutch physician was stationed at that time in the Dutch settlement in Java. He noted a peculiar outbreak of disease among fowls that were being fed cooked rice discarded from the kitchen of the hospital to which he was attached. The symptoms were characteristically like those of natives who developed beriberi and the malady was designated by Eijkman as polyneuritis gallinarum. This astute observer promptly followed up these earlier observations by an investigation that showed that a diet of polished rice always induced polyneuritis in birds, and that it could be averted or cured by the use of unmilled rice or rice polishings in the food. For the first time, Harrow writes, physicians had a readily available means of studying a disease that had wrought havoc to vast populations. A new era in experimentation was begun.

It matters little that Eijkman failed to identify correctly the substance in rice polish and other food materials that prevents experimental polyneuritis. The essential feature of his researches is the application of new methods of study and the revision of scientific points of view. The soil that Eijkman prepared lay fallow for more than a decade before noteworthy progress followed. Funk, in particular, took up the question of the nature of the active principle—the protective or curative agent that averts beriberi—in 1911. From this has developed the present-day knowledge of the vitamins.

REPRODUCTION AND EXCESS PROTEIN IN THE DIET

The question of the most favorable amount of protein in the diet is not new. In the first few years of the present century the advocates of a liberal protein allowance, largely in Germany, were opposed by the proponents of the strict limitation of protein, the chief of whom were Chittenden in this country and Hindhede in Denmark. When, on the other hand, through the classic studies of Fischer, Kossel, Osborne and Mendel, and Hopkins the importance of quality of protein was emphasized, the question of quantity was lost sight of temporarily. However, the present decade has seen a revival of interest among students of nutrition in the effects of high concentrations of dietary protein on the organism. The problem has been attacked both in the laboratory with experimental animals and in the clinic, and vast amounts of data have accumulated. Since the kidney is the organ primarily involved in the excretion of the products of the metabolism of protein, the attention of investigators in this field has naturally been focused on the possibility of demonstrating a nephrotoxic action of excessive concentrations of this foodstuff. In some of the studies a more definite answer has been sought by removing one kidney in order to increase the burden on the remaining one. However, in view of the apparent simplicity of the thesis, the results have been surprisingly inconclusive. After studying the available evidence, two reviewers[1] have come to the none too sure conclusion that most of the data favor the view that high levels of protein in the diet do not exert an unfavorable influence on the kidney.

[1] Mitchell, H. H.: Biochemistry of the Amino Acids, 1929, p. 550 et seq. Du Bois, E. F.: J. Am. Diet. A. 4: 53, 1928.

In spite of the importance of the kidney in protein metabolism, it is possible that other body functions may be altered by unduly large amounts of dietary protein. In a recent report by Parsons, Smith, Moise and Mendel[2] are given the results of an extensive investigation of the influence of protein-rich rations on various phases of the reproductive cycle. The rations, which contained 16, 40 and 70 per cent of protein, were otherwise complete and some of the animals (albino rats) were subjected to unilateral nephrectomy. It was early observed that high concentrations of protein had no deleterious effect on ovulation, the estrous cycle being regular even in the animals with only one kidney. Gestation likewise proceeded without toxic symptoms even on the extreme rations employed. Lactation, however, was not even approximately successful on the diet richest in protein until further additions of vitamin-containing materials were made. Thus it appears that, of the various phases of the reproductive cycle, only lactation is adversely affected by the combination of greatly heightened protein metabolism and reduction in renal tissue.

Significant observations on the kidneys of mother and offspring were made also by Parsons and her co-workers. The average degree of enlargement of the remaining kidney after unilateral nephrectomy and after sixty days on the protein-rich diet was 106 per cent in those females which had no young, 111 per cent in those in which only gestation was permitted, and 154 per cent in the group that experienced both gestation and lactation. This last response of the kidney to high concentration of protein is notably larger than that occurring in male rats under similar dietary conditions and points to a definite effect of milk production on those processes in the body with which renal function is associated. Twelve animals with one kidney were given the protein-rich diet for periods ranging from 106 to 184 days, during which one or more litters of young were reared. Histologic examination of the remaining kidney at necropsy showed severe lesions in only three cases. The kidneys of the young of a group of animals consuming the protein-rich ration were compared with those of the offspring of another group on the low-protein food before the young had begun to eat the mother's ration. The ratio of kidney weight to body weight of the first group was significantly greater than that of the second group. It seems, therefore, that the substances which influence the size of the kidney during heightened protein metabolism are transmitted through the mother's milk.

From these studies it appears that not until the maternal organism feels the stress of the elaboration of milk do the circumstances surrounding the high level of protein metabolism exert an unfavorable influence. In spite of the augmented degree of nitrogen metabolism, the reduction of functioning renal tissue and the stress of reproduction, the kidneys show relatively little damage. The enlargement of the maternal kidney as well as that of the kidneys of the suckling young can be looked on as a result of the physiologic response to increased functional demands. These studies emphasize anew the remarkable factor of safety possessed by the renal excretory apparatus and also the intensity and the widespread nature of the demands for lactation.

Current Comment

THE SYMPTOMS OF VITAMIN A DEFICIENCY

Most of the symptoms of so-called dietary deficiencies developed by a shortage of vitamins in the food have been established by experiments on animals. To what extent they are actually represented in human disorders is only slowly becoming known. In the case of man, defects in nutrition are likely to exhibit simultaneously multiple symptoms that have diverse causes, so that it becomes difficult to disentangle the manifold etiologic factors in the disease syndrome. The investigator who deals with experimental animals is able to select his dietary conditions so as to exclude many of the simultaneous variables that might modify the result. This helps to explain why his observations are not always matched in the categories of human disorder. There is little doubt regarding the importance of the fat-soluble vitamin A in human nutrition; yet the most conspicuous of the manifestations of vitamin A deficiency in rats, on which the pioneer investigations have been conducted, is the characteristic ophthalmia, a phenomenon only rarely recorded for man. It is significant, therefore, to learn from observations of Tilden and Miller[1] at the Rockefeller Institute for Medical Research, New York, what the deficiency symptoms are that monkeys tend to manifest when vitamin A is missing from their diet. The first symptom of illness noted in the monkeys receiving the low vitamin A ration was loss of weight, which was followed sooner or later by loss of appetite and finally by colitis and death. There was no xerophthalmia, sinusitis or mastoiditis, and abscesses of the tongue were not found in any of the animals. Keratomalacia and hemeralopia in human beings have been attributed to deficiency of the A factor in the diet. Other conditions in animals or man that have been attributed to this cause are diarrhea, respiratory disturbances, urolithiasis, calcification of kidney epithelium, edema and gastric carcinomas. With regard to the signs of depletion of vitamin A reserves in monkeys, Tilden and Miller say that in one respect, at least, the response of the monkey is the same as that of the rat and the guinea-pig; namely, in the epithelial metaplasia which manifests itself particularly in the respiratory and genito-urinary tracts. The New York investigators remark that the total absence of eye lesions in the monkeys, and of infections of the sinuses, middle ear and glands of the tongue, as compared with the rather frequent occurrence of these signs in rats, is of especial interest. A similar observation has been made by Wolbach and Howe with respect to the guinea-pig. In view of the delicacy of the monkey, as compared with the rat, however, and the possibility that the monkey succumbs to the intestinal condition before the development of other symptoms, Tilden and Miller are not altogether sure that the monkey may not, under certain conditions, manifest the nutritional failure in other ways. Perhaps in view of the report just reviewed, more attention should be centered on a possible interrelation between alimentary symptoms and vitamin A deficiency in man.

RECENT STUDIES IN UNDULANT FEVER

Hasseltine[1] of the United States Public Health Service has recently summarized the results of his field investigations of undulant fever in the United States. The disease was recognized in every state of the Union during 1929. Epidemiologic data indicate that the cases of undulant fever as they occur in this country can be divided into three main groups: the milk group, without significant exposure to live stock or animal carcasses (mostly urban cases); the farm group, in which are included the rural cases having direct contact with live stock, and the meat group, consisting of urban cases having direct contact with live stock or carcasses. In regard to the question as to the relative pathogenicity of the types of *Brucella* organisms which may be found in raw milk, Hasseltine says: "It makes no difference whether a patient receives a bovine, porcine or caprine type of *Brucella* through the raw milk he consumes; the fact that he contracts a preventable disease through such channels is what makes the matter of first importance." Hasseltine further says: "In cities having only a portion of their milk supply pasteurized, undulant fever has picked out the user of raw milk with as much precision as smallpox picks out the unvaccinated." Contact with infected animals, particularly with infected hogs, frequently results in infection; such cases are usually severe and sometimes fatal. The application of the agglutination test to cattle, and the segregation and ultimate elimination of those reacting positively, appears to be the logical method for eliminating the infection at its source. It is probable that only a few of the infected cows will escape detection by the agglutination test, and these will probably be found on retests of the herd. Hasseltine states that, to the health official, the greatest weakness of the procedure of examination of live stock and the elimination of infected animals is the length of time it will take to accomplish this gigantic task. For the protection of the health of the people it is necessary to rely on such measures as education of those whose occupation brings them in direct contact with infected animals, and on pasteurization to prevent milk-borne cases. It is further emphasized that examination of milk by ordinary bacteriologic methods does not reveal the presence of *Brucella* therein, as these organisms grow too slowly to appear visible in twenty-four hours. Therefore, a milk that has an exceedingly low bacterial count may be heavily contaminated with the organisms of undulant fever. Since the organism has its source in the cow's udder, no amount of cleanliness, inspection or sterilization of utensils will be of any account unless the cow is known to be free from *Brucella* infection. Hasseltine's studies have led him to the conclusion that the pasteurization of milk renders it safe and takes care not only of undulant fever but of all other communicable diseases transmitted by milk.

CARDIAC FIBROSES

In the St. Cyres lecture, Dr. John Cowan[1] recognized three sources of fibrosis of the heart: myocarditis, ischemic necrosis and syphilis. Myocarditis is found not only as a result of rheumatic infection but also, though less commonly, as a complication of many acute infections: pneumonia, pleurisy, diphtheria, sepsis, smallpox, typhoid, scarlatina and blackwater fever. Syphilis may affect the heart muscle through the formation of gummas, though this is rare. The common attack on the heart muscle is through disease of the coronary arteries with resulting ischemia. The damage resulting from occlusion of a coronary artery depends on the rapidity with which it is occluded, a slower process giving better opportunity for the development of anastomotic circulation. Angina pectoris is regarded as the symptom of an ischemic heart, the evidence of a local anoxemia. The doctrine of Wenckebach that "in angina pectoris we should not look for a bad heart muscle; the part of the aorta adjoining the heart is the seat or the origin of the pain"[2] is ignored. Dr. Cowan accepts the theory of an ischemic origin of the pain on the experimental evidence of MacWilliam[3] and the clinical and necropsy analysis of Keefer and Resnik.[4] Under conditions of rest and tranquillity it is supposed that the heart muscle may receive an adequate supply of oxygen, but granted exertion or a slight rise in blood pressure from excitement or other cause and the supply of oxygen becomes deficient, the pain of angina is the result. In diagnosis the electrocardiogram is of value only if the fibrosis happens to strike the bundle branches; in other situations it will do nothing to deform the electrocardiographic picture. In the former case some clinical evidence of heart block may be expected and, indeed, in almost all cases of myocardial fibroses some changes in heart sounds or in the outline of the heart are to be expected. The prognosis is difficult; although early death is the rule, some patients recover a degree of health and activity. Dr. Cowan mentions one patient who carried a full heart block for thirty years until his death at the age of 70. In general the prognosis will depend on the cause of the ischemia or inflammatory fibrosis and its amenability to treatment. Syphilitic lesions may improve notably under antisyphilitic treatment, while atheromatous lesions cannot be dissipated, though the progress of the sclerosis

may be delayed. The final issue of acute myocardial disease, whether inflammatory or ischemic, depends on the treatment of the initial attack. Dr. Cowan keeps his rheumatic patients in bed for two months after the temperature and pulse rate have returned to normal. Similarly, rest is indicated after an infarct and must be absolute, even though it is necessary to employ sedatives to this end. Rest again in cases of insidious origin will delay critical effort and give time for the development of anastomotic circulation. When exercise is resumed it must be kept well within the diminished capacity of the damaged heart.

Association News

ABSTRACT OF MINUTES OF MEETING OF BOARD OF TRUSTEES HELD IN CHICAGO, NOV. 13 AND 14, 1930

The Board of Trustees met in Chicago on Thursday and Friday, Nov. 13 and 14, 1930.

MEMORIAL FOR PHYSICIANS WHO SERVED IN THE WORLD WAR

A committee was appointed, composed of Drs. Olin West, Morris Fishbein and William Gerry Morgan, to institute a campaign to raise $10,000 by popular subscription among the members of the Association, with the assistance of the state societies, to provide in Pershing Hall—America's Memorial to the Commander-in-Chief, Officers and Men of the American Expeditionary Forces, which is under construction at 49 Rue Pierre-Charron, Paris, by the American Legion Building Paris, Inc.—a suitable memorial to the officers and men of the Medical Corps who served and gave their lives in the World War.

BUREAU OF ECONOMICS

Applications for the position of Director of the Bureau of Economics were considered, but definite action was postponed pending further consideration.

DUTIES OF COMMITTEE ON POISONOUS GASES ENLARGED

The duties of the Committee on Poisonous Gases were enlarged to include any hazard to health or life from poisonous substances developed through modern activity.

COOPERATION BETWEEN FEDERAL AND STATE GOVERNMENTS IN PUBLIC HEALTH ACTIVITIES

Consideration was given to the resolution passed by the House of Delegates providing that the Board of Trustees initiate, as speedily as practicable, a movement to enlist every state medical association and county medical society, and every member of the medical profession in a movement to carry into effect the policy of the American Medical Association with respect to cooperation between federal and state governments in public health activities. The Board feels that everything possible is now being done along these lines.

FIRE IN PROPERTY OWNED BY ASSOCIATION

A report was received concerning two fires which had recently broken out in buildings east of the headquarters office that are owned by the Association. One of these buildings—that adjoining the headquarters—has been remodeled in accordance with authorization from the Board; an opening has been made into it from the headquarters, and it is being used to house one department and for storage purposes. The Board referred to a committee comprising the General Manager, the Business Manager and the local Trustee the matter of reconditioning or razing the other buildings that have been damaged by fire.

CHAIRMAN OF LOCAL COMMITTEE ON ARRANGEMENTS

The Board confirmed the nomination by the Philadelphia County Medical Society of Dr. George C. Yeager as chairman of the Local Committee on Arrangements for the Philadelphia session of the Association in 1931.

ACKNOWLEDGMENT OF GIFT TO HYGEIA

The appreciation of the Board was expressed to a physician who has contributed more than $5,000 to the Association within the last three years for subscriptions to *Hygeia,* mainly for libraries, and who prefers not to have his name revealed.

APPROPRIATION FOR INSPECTION OF HOSPITALS FOR THE CARE OF MENTAL PATIENTS

An appropriation of $20,000 was made available for the Council on Medical Education and Hospitals for an inspection of hospitals devoted to the care of mental patients, provided for in the resolution adopted by the House of Delegates at the Detroit session.

COMMITTEE ENLARGED

The committee appointed to cooperate with federal departments concerning regulations under the Volstead Act was enlarged by the addition of Dr. J. H. J. Upham of Columbus, Ohio, and Dr. Henry A. Christian of Boston.

The chairman of the committee, Dr. William H. Mayer of Pittsburgh, and the executive secretary of the Bureau of Legal Medicine and Legislation, Dr. W. C. Woodward, appeared before the Committee on Law Observance and Enforcement, November 12, and protested against the interference by legislation with the prescribing by qualified physicians of agents that they conscientiously believe to be useful in the practice of medicine.

RESIGNATION OF DR. DILLEHUNT FROM COUNCIL ON PHYSICAL THERAPY

The Board accepted the resignation of Dr. Richard B. Dillehunt of Portland, Ore., who asked to be relieved because of his inability to give to the affairs of the Council on Physical Therapy the attention they require, and to attend the meetings of the Council, owing to the great distance to Chicago.

DANGERS INVOLVED IN THE INDISCRIMINATE USE OF ACETANILID AND BARBITAL

A report from the Council on Pharmacy and Chemistry, recommending that the public be educated concerning the dangers involved in the indiscriminate use of acetanilid, especially of acetanilid-containing nostrums, and barbital was adopted.

REPORT OF CHAIRMAN OF COMMITTEE ON ENTERTAINMENT AT ANNUAL SESSIONS

The report of Dr. Austin A. Hayden, chairman of the Committee on Entertainment at Annual Sessions, covering tentative arrangements for the President's reception on Thursday evening of the week of meeting, as well as for entertainment in the form of supper-dancing and cards to be available to the visiting physicians and their guests at a nominal fee throughout the week, was adopted and placed on file.

MISCELLANEOUS BUSINESS

Other matters were given careful deliberation; some were referred to committees, and action on some was postponed.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10:15 on Tuesday, 10:30 on Thursday and 10 on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

December 1.	The Prevention of Some of the Common Diseases of the Skin.
December 2.	Cancer Control — A Public Health Problem.
December 4.	The Proposed Home for One-Legged Canary Birds.
December 6.	The Problem of Sweets for Children.

Five Minute Health Talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

December 1.	How's Your Digestion?
December 2.	Personal Preferences.
December 3.	Commendable Cooks.
December 4.	More About Cooks.
December 5.	Overconfidence.
December 6.	The Pace That Kills.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Licenses Revoked.—At a meeting of the State Medical Board of the Arkansas Medical Society, November 11, the license to practice medicine in the state of Dr. Abraham M. Goldstandt, Columbus, Ohio, was revoked on the grounds that the credentials on which this certificate had been issued were revoked in Ohio, April 1, for grossly unprofessional or dishonest conduct. The license of Dr. William W. Hornsby, North Little Rock, was also revoked at this meeting. Dr. Hornsby had been convicted and sent to prison for violating the narcotic act.

Society News.—The First Councilor District and Northeast Arkansas Medical Society was entertained by the Craighead-Poinsett County Medical Society, at Tyronza, October 15; among other speakers were Drs. William R. Bethea, Memphis, Tenn., who spoke on "X-Rays as a Benefit to the General Practitioner," and Jones H. Lamb, Paragould, "Methods of Treating Arterial Hypertension."——The Arkansas County Medical Society was addressed at DeWitt, October 14, by Drs. Milton C. John, Stuttgart, on icterus neonatorum; Robert H. Whitehead, infantile paralysis, and C. W. Rasco, diphtheria.——Dr. George B. Fletcher discussed the outstanding symptoms of mental disease before a recent meeting of the Hot Springs County Medical Society at Malvern.——The Independence County Medical Society was addressed at Batesville, October 13, by Drs. Thomas N. Rodman on "Cardiac Arrhythmias"; John M. Hooper, "Carcinoma of the Gallbladder"; O. S. Woods, Salem, "Tumor of the Mediastinum," and Frank A. Gray, "Diagnosis and Treatment of Carcinoma of the Uterine Cervix."

CALIFORNIA

Hospital News.—The Ernest V. Cowell Memorial Hospital was dedicated, October 21, at the University of California, Berkeley; the dedication was a part of the ceremonies in connection with the inauguration of Robert Gordon Sproul as president of the university.

Society News.—Dr. Arthur Elmer Belt presented a motion picture on "The Habits and Urinary Tract of the Cetaceans" before the Los Angeles Surgical Society, November 14; Dr. David G. Ghrist, Rochester, Minn., spoke on "The Present Status of Therapy in Chronic Rheumatic Diseases with Special Reference to Surgical Procedures."——The San Diego County Medical Society was addressed, November 12, by Dr. Howard L. Updegraff, Hollywood, on "Methods of Reconstructive Surgery."——At the eighty-third semiannual meeting of the Southern California Medical Association in Long Beach, October 31-November 1, the following officers were elected for the ensuing year: Drs. Fred B. Clarke, Long Beach, president; William H. Barrow, San Diego, and Philip H. Stephens, Los Angeles, vice presidents, and Carl R. Howson, Los Angeles, secretary. The next annual meeting will be held at Coronado in April, 1931.——The Alameda County Medical Association was addressed in Oakland, November 17, by Drs. William W. Cross, Jr., Oakland, on urinary tract obstruction; Charles L. McVey, on syphilis of the mouth, and Harry J. Templeton and Charles J. Lunsford, on "Sporotrichosis in California."——Rear Admiral Edward R. Stitt, U. S. Navy, addressed the Los Angeles County Medical Society, November 20, on annual health examinations in the navy during the past twenty years.——The Clinical and Pathological Society was addressed in Los Angeles, November 25, among others, by Dr. Charles C. Browning on "Extensive Emphysema Throughout the Muscles and Subcutaneous Condition of the Chest, Secondary to Pathologic Fracture of the Rib," and Dr. Wilbur B. Parker, "Intravenous Pyleography by Means of Uroselectan."——Drs. Hans E. Schiffbauer and John W. Nevius addressed the Trudeau Society, November 25, on "Resection of First Rib Anteriorly with Phrenic Exeresis" and "Problems in Artificial Pneumothorax," respectively.——Among others, Drs. Eliot Alden, Los Angeles, and Douglas Quick, New York, addressed the Hollywood Academy of Medicine, December 3, on "Present Status of Cancer of the Breast" and "Intra-Oral Malignancies—Diagnosis and Treatment," respectively.

DELAWARE

Health at Wilmington.—Telegraphic reports from seventy-eight cities with a total population of thirty-five million to the U. S. Department of Commerce, for the week ending November 15, indicate that the highest mortality rate was for Wilmington, and the mortality rate for the group of cities as a whole, 12.1. The mortality rate for Wilmington for the corresponding week last year was 13.9, and for the group of cities, 11.3. The annual rate for seventy-eight cities was 11.9 for the forty-six weeks of 1930, as against a rate of 12.7 for the corresponding weeks of 1929. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits, or that they have a large Negro population, may tend to increase the death rate. The rates published in this summary are based on midyear population estimates derived from the 1930 census. Cities whose population was found to be less than was indicated by estimates heretofore used will therefore appear as having a higher death rate than usual, even though there may have been no material increase in the actual number of deaths.

ILLINOIS

Campaign Against Cancer.—Dr. Andy Hall, state health director, has announced that five state-wide medical and health organizations have formed an agreement to carry out a vigorous anticancer campaign over the state. The cooperating organizations are the Illinois Department of Public Health, the educational committee of the Illinois State Medical Society, the Educational Association on Cancer, the Illinois branch of the American Society for the Control of Cancer, and the University of Illinois College of Medicine. Special emphasis will be made in an educational drive to halt the increase of cancer on visible parts of the body. The program will include the publication of an illustrated booklet for free distribution throughout the state and for the building of a mobile exhibit made up of wax models, actual specimens, pictures and charts which show cancer of accessible parts of the body, in all of its recognized stages and forms, and a cancer week program.

Society News.—The Southern Illinois Medical Association held its fifty-sixth annual meeting in Mascoutah, November 6-7. The program included papers by Drs. John Niess, Jr., Carmi, on "Effects of Tonsillectomy on the General Health"; Quitman U. Newell, St. Louis, "Remarks on Treatment of Sterility in the Female"; Clyde E. Purcell, Paducah, Ky., "Foreign Bodies in the Respiratory and Food Passages"; William D. Chapman, Silvis, "Medical Organization and Practice"; William H. Evans, Murphysboro, "The Family Physician and the Ex-Service Man." The Canti and Lewis cancer films and Dr. DeLee's three reel film on "The Toxemias of Pregnancy" were shown. Officers elected were president, Dr. Charles W. Hall, Mount Vernon; vice presidents, John E. Reed, Benton, and Charles S. Skaggs, East St. Louis, and secretary, William J. Benner, Anna. The next annual meeting will be held in Olney.——"Syphilis of the Nervous System" was the subject of Dr. H. Douglas Singer, Chicago, November 19, before the Will-Grundy County Medical Society.

Chicago

Society of Allergy Organized.—The Chicago Society of Allergy, which has been meeting informally, was formally organized, November 12. Meetings will be held the third Monday night of each month and scientific programs will be presented. All interested are invited. Drs. Harry L. Huber and Leon Unger were elected president and secretary, respectively.

Society News.—Dr. Herman L. Kretschmer delivered the Mayo Foundation lecture on neurology at Rochester, Minn., November 3, on "Diseases of the Urinary Tract in Infancy and Childhood."——The fifteenth annual meeting of the Institute of Medicine of Chicago will be addressed, December 2, by Dr. George E. Shambaugh on "The Problem of Deafness," and Dr. George Burgess Magrath, Boston, "Some Personal Experiences as a Medical Examiner."——Dr. Abraham Myerson, Boston, addressed the Illinois Society for Mental Hygiene, November 25, on "Inheritance and Environment: Their Effect on Personality."——Madame N. Dobrovolskaya-Zavadskaya of the Curie Institute, Paris, France, lectured at Northwestern University Medical School, November 24-25, on "Some Important Notions from Radiology" and "About the Heredity of Cancer."

Patients Desired for Study of Pneumonia and Hypertension.—The department of medicine of the University of Chicago, in the pursuance of studies of pneumonia, has set aside beds in the Albert Merritt Billings Hospital for the admission, free of charge, of patients whose financial circumstances warrant such consideration. The Lasker Foundation and the department of medicine of the university, which has undertaken a long term of clinical study of hypertension, have arranged for the admittance, free of charge, of cases to the Max Epstein Clinic. The type of patients desired are those less than 40 years of age with high blood pressure and without other symptoms, and patients less than 40 years of age with high blood pressure and other indications of chronic Bright's disease. Such patients will be admitted as ambulatory and will be hospitalized only if necessary. Patients with a fair prospect of being available over a period of years will be given preference.

MARYLAND

Sir D'Arcy Power Lectures at Johns Hopkins.—A series of lectures is being given at the Institute of the History of Medicine, Johns Hopkins University School of Medicine, by Sir D'Arcy Power, England, honorary librarian of the Royal College of Surgeons. His subjects, November 19 and 25, were "Essentials of Medical Biography" and "Medical Bibliography," respectively. He will speak on "The Meals of Our Ancestors," December 2; "Aristotle's Masterpiece," December 3; "Medical Iconography," December 10, and "The Growth of a Hospital," December 17.

Society News.—The West Baltimore Medical Society was addressed, October 21, by Drs. Llewellyn W. Lord, Baltimore, on "End-Results in the Treatment of Acne with X-Rays"; John A. Evans, Baltimore, "Differential Diagnosis of Pathology with the Thorax by Means of the X-Ray," and John F. Hogan, Baltimore, "The Peculiar Course of a Bullet Lodging in the Epididymis."——The third meeting of the Baltimore and Washington Urological Society was held, November 7, in Baltimore; Washington physicians delivered the papers, which were discussed by Baltimore physicians; Drs. Robert Arthur Hooe, Washington, D. C., spoke on "Prostatectomy Complicated by Acidosis"; Horatio N. Dorman, "Hydronephrosis with Aberrant Polar Vessel"; Ralph M. LeComte, "Papilloma in a Vesical Diverticulum," and Charles P. Howze, "Multiple Calculi Within the Utricle: Operation and Results."

MASSACHUSETTS

Society News.—The annual meeting of the Massachusetts Society for Mental Hygiene was addressed, November 18, in Boston, by Sheldon Glueck, Ph.D., on "Modern Trends in Criminology," and Dr. George H. Preston, commissioner of mental hygiene of Maryland, on "Community Mental Hygiene."——The Massachusetts Psychiatric Society was addressed, October 24, by Dr. Albert Warren Stearns on "A State Program of Crime Prevention."

Dr. Duke-Elder to Lecture at Harvard.—Two lectures on "Recent Work on the Metabolism of the Eye" will be delivered at Harvard University Medical School, under the auspices of the Howe Laboratory of Ophthalmology, by Dr. William Stewart Duke-Elder, London, England, in Amphitheater E. The lectures will be given December 15 and 17 on "Physiologic Aspects" and "Clinical Aspects," respectively. Dr. Duke-Elder is honorary research associate at University College, London, and lecturer of ophthalmology, University of London.

Hospital News.—The Somerville Hospital, Somerville, is soon to have an addition to its surgical and obstetric departments involving an expenditure of $150,000, it is reported.——Ground has been broken for the Jackson Memorial Building, a forty-five bed hospital for children to be used by the Boston Floating Hospital for all year care. At the same time the New England Medical Center building, of which the Jackson Memorial will be a part, was started. The Center building will include, among other things, professional services and a twenty bed observation ward. The Tufts College Medical School is the other unit of the New England Medical Center.

MICHIGAN

Licenses Reinstated and Revoked.—The Michigan State Board of Registration in Medicine reports that the license of Dr. John J. George was reinstated, October 15; that Dr. John L. Estabrook's license was revoked, owing to his having obtained money from his patients and others on false pretenses; that Dr. George W. Leuschner's license was revoked, owing to his association with an unregistered practitioner of medicine, and unprofessional and dishonest conduct in his practice. Dr. George W. Bolkcom, Minneapolis, the board stated, made periodic tours throughout the state of Michigan, advertising in the local newspapers before his visits; his license was revoked, owing to his unprofessional and dishonest conduct in his practice. Dr. Sidney H. Culver's license was revoked, as he had been convicted on a charge of abortion, May 29, at Mason.

Five Year Research on Dental Problems.—Representatives of the medical and dental professions held a conference on cooperative research in Detroit, September 7-8. The conference, sponsored by the Children's Fund of Michigan and the Merrill-Palmer School, inaugurated an enlarged plan of research on the growth of the dental apparatus and related parts under the direction of Samuel J. Lewis, D.D.S., following a preliminary five year study recently completed. The program, to be financed by the Children's Fund, comprises a study of growth fluctuations based on taking the impressions of teeth and dental arches and anthropometric measurements of the head and face of a group of 500 children, ranging in age from 2 to 10 years, once a year for five years. Intra-oral and extra-oral dental roentgenograms of the entire group will be taken in a study of the shedding of deciduous teeth, the eruption of the permanent teeth and the development of the third molars. Roentgenograms of the hands and elbows of the entire group will be taken to secure correlations between dental, carpal and epiphyseal growth. Impressions of the upper arches and roentgenographic studies of the sinuses and jaws will be made of a group of new-born babies to secure measurements for comparing the growth curves of dental arches and other growth curves of the human body. The impressions of teeth and dental arches of parents of a selected group of fifty children taken over a five year period will be the basis of studies of the part played by heredity in the dental growth and development. The study will center also on the relation between diet and dental growth in caries. The Merrill-Palmer School, the Children's Hospital of Michigan, the Protestant Orphanage of Detroit and the Methodist Children's Village are cooperating in supplying children and records for the study.

MINNESOTA

Reprints of Clinical Conferences.—The *Journal-Lancet* has announced that the series of clinical pathologic conferences which it has published monthly during the year will soon be available in index, loose-leaf reprints. About 250 cases will appear each year. The work will be under the direction of Dr. Elexius T. Bell, professor of pathology, University of Minnesota Medical School, Minneapolis.

Illegal Practitioner Sentenced.—The Minnesota State Board of Medical Examiners recently reported that Elmer Mason entered a plea of guilty to a charge of practicing healing without a basic science certificate at Winona. Mason was the leader of a group of Indian doctors who, during July and August, sold between four and five thousand dollars' worth of Indian roots and herbs to the citizens of Fillmore and Houston counties. Judge Gates sentenced Mason to serve three months at hard labor in Houston County. Another member of the group has completed a sixty day sentence in the county jail of Houston.

MISSOURI

Court Reverses Board's Decision.—Circuit Judge Hall, St. Louis, reversed the state board of health's decision, October 20, in revoking the license to practice medicine in Missouri of Dr. William R. Harman, Springfield. Dr. Harman's license had been revoked in June on the charge that he had produced an abortion. (The Journal, July 5, p. 55.)

Society News.—The Kansas City Society of Ophthalmology and Otolaryngology recently started the publication of a monthly bulletin. Dr. Burt R. Shurly, Detroit, addressed the society, September 18, on "Some Observations on Vitamin Deficiency, Relative to the Eye, Ear, Nose and Throat, with Especial Reference to Vitamin A. Deficiency in Diseases of the Paranasal Accessory Sinuses, from the Research Laboratory of the Detroit College of Medicine."——The fall tournament of the Physicians' Golf Club and the Dentists' Golf Club of St. Louis was held at the North Hills Country Club, October 17. A team of twelve members from each club played for the Dr. Rutherford B. H. Gradwohl trophy, the physicians winning. This was the second contest between the clubs. The first tournament, July 11, resulted in a tie. These facts are engraved on the trophy, which will be displayed at the St. Louis Medical Society.——Dr. Wilfred E. Martin addressed the Lafayette County Medical Society, October 28, at Odessa on "Diagnosis and Treatment of Infantile Paralysis."——"New Methods in Treatment of Fractures" was the subject of Dr.

Myron O. Henry, Minneapolis, before the Jackson County Medical Society, November 18; the society was addressed, November 25, by Drs. Julius Frischer, Kansas City, on "Transurethral Surgical Diathermy for Prostatic Hypertrophy"; John Wesley Field, "Clinical Psychology," and Otto J. Printz, "Surgical Treatment of Peptic Ulcers." Dr. Ferdinand C. Helwig conducted a clinical pathologic conference.

NEW YORK

Society News.—"Kidney Disease from the Newer Concepts of Its Diagnosis and Treatment" was the subject of Dr. William Goldring's address before the Medical Society of the County of Nassau, October 28.——Dr. Charles Ward G. Crampton, New York, addressed the Medical Society of the County of Albany, November 18, on "Making the Periodic Health Examination Practical," and Dr. Nellis B. Foster, New York, "Some Diseases Recognizable in the Preclinical Stages."——The Medical Society of the County of Kings was addressed, November 18, by Dr. Arlie V. Bock, Boston, on "Physiological Changes Induced by Exercise"; Dr. Robert Tait McKenzie, Philadelphia, "Exhaustion as Shown in the Face," and Charles E. Barker, Grand Rapids, Mich., "Value of Exercise from the Preventive and Remedial Viewpoint." An afternoon session, open to the public, was addressed by the same speakers on "Exercise and Health," "Fatigue and How to Recognize It," and "How to Live One Hundred Years," respectively.——A symposium on peptic ulcer was conducted before the East New York Medical Society, November 24, by Drs. Isidore A. Feder, Reuben Finkelstein and Albert A. Berg.

Hospital Referendum Carries.—Voters of Nassau County carried the hospital referendum by a vote of 8 to 1, November 4, which approved of a bond issue of $1,750,000 for the erection of a 200 bed county general hospital which should have special provisions for the care of contagious and venereal diseases, chronic, curable and convalescent patients and the treatment of psychopathic cases. Ninety thousand dollars of the sum will be used for land and the remainder for buildings. The proposed hospital will cost each taxpayer only 19 cents for each $100 of assessed valuation, should the entire amount be paid in one year. The present general hospitals in Nassau County are private institutions, and the only one operated by the county for the care of the sick is the tuberculosis sanatorium at Farmingdale. The new appropriation marks the culmination of eight years of effort on the part of the Medical Society of Nassau County to obtain more adequate hospital accommodations. A particularly interesting feature of the campaign and an important factor in securing sympathetic public interest was the medical society's exhibit at the annual county fair, in which special emphasis was placed on the need of a new county hospital. The project was further stressed by the distribution of hand bills comparing present facilities with minimum requirements and describing the size, nature and cost of the proposed institution.

New York City

Third Harvey Lecture.—Dr. G. Elliot Smith, University College, London, England, will deliver the third Harvey Society Lecture at the New York Academy of Medicine, December 4, on "The Peking Man."

Dr. Dougherty Honored.—Dr. Daniel S. Dougherty was honored, November 6, at a testimonial dinner tendered by his colleagues on the medical board of City Hospital on the occasion of his retirement from active service as attending otolaryngologist. Dr. Dougherty has been a member of the board for twenty-three years, during fourteen of which he served on its executive committee. He has been professor of otology in the New York Polyclinic Medical School and Hospital during the past decade and, since 1916, served as secretary of the Medical Society of the County of New York and last year became its director of activities. In 1925, he became secretary of the state medical society.

Dr. Gregg Appointed Director of Medical Sciences.—Dr. Alan Gregg has been appointed director for the medical sciences of the Rockefeller Foundation. He will occupy the position vacated by the death, February 16, of Dr. Richard M. Pearce, Jr., in whose work he had for many years closely participated as associate director for the medical sciences. Dr. Gregg will assume his new duties, January 1. Graduating from Harvard University in 1911, and from the Harvard Medical School in 1916, Dr. Gregg, after a year as intern at the Massachusetts General Hospital, served overseas and was made a captain in the medical reserve corps of the British Army. On March 1, 1919, he first took up his work with the Rockefeller Foundation as a field staff member of the International Health Board. For three years he was actively engaged in public health work in Brazil. In 1922, he became associate director of the division of medical education. After making studies of medical education in a number of countries which included Colombia, Mexico and Italy, he was stationed at the Paris office of the Rockefeller Foundation, from which since 1925 he has been directing Rockefeller Foundation work in the medical sciences in Europe.

OKLAHOMA

Society News.—The next annual session of the Oklahoma State Medical Association will be held, May 11-13, 1931, at Oklahoma City with headquarters in the Shrine Temple.——The Tulsa County Medical Society was addressed, November 10, by Dr. Dean W. LeMaster on "Treatment of Diabetes with Low Fat and High Carbohydrate Diets."——The third annual clinic day of the Tulsa Academy of Medicine was held at Morningside Hospital, Tulsa, November 18; Dr. Meyer Wiener, associate professor of clinical ophthalmology, Washington University School of Medicine, St. Louis, conducted a clinic in the afternoon on plastic surgery of the eyelids and spoke in the evening on "Certain Eye Conditions of Importance in the Work of the General Practitioner."——Dr. Fred G. Dorwart addressed the Muskogee County Medical Society, October 26, on heart conditions.——The Garvin County Medical Society was addressed, October 22, in Pauls Valley by Dr. Floyd Gray, Oklahoma City, on obstetrics.——The Okmulgee-Okfuskee County Medical Society was addressed at Okemah, October 20, by Drs. Frank LeRoy Carson, Shawnee, and Edward K. Witcher, Tulsa, on "Sodium Amytal Anesthesia" and "Use of Iodized Oil in Chronic Pelvic Disorders," respectively.——Drs. Hugh G. Jeter and Willis K. West, both of Oklahoma City, spoke on nephritis and deformities of the arm, respectively, before the Caddo County Medical Society, October 22, at Anadarko.——The Lincoln County Medical Society was addressed at Chandler, October 1, by Drs. Horace Reed, Oklahoma City, and Marvin B. Glismann, Okmulgee, on goiter and obstetrics, respectively.

OREGON

Food Poisoning Traced to Pie.—An explosive gastrointestinal outbreak occurred at Reed College, Portland, during September. A large number of students became violently ill, due to eating contaminated pie. All the blood specimens from patients at the college that were tested gave some agglutination with *Bacillus paratyphosus* B but not with *Bacillus paratyphosus* A. Twenty-nine of the cases required hospital treatment, and forty or fifty were cared for in homes or dormitories. There were no fatalities. Transmission of the infecting agent was supposed to be due to mice.

Society News.—The Portland City and County Medical Society was addressed, October 1, by Drs. William K. Livingston on "Studies of the Sympathetic Nervous System"; Drs. Albert L. Mathieu, Frank E. Trotman, Howard D. Haskins, Edwin E. Osgood and Joyce Albert presented a joint paper, October 15, on "Sedimentation Rates in Gynecology and Obstetrics: Results by the Modified Westergren Technic in Over 2,200 Determinations on 1,200 Patients"; Dr. John C. Brougher, Vancouver, Wash., spoke on "Parathyroid Tetany."——Dr. Goodrich C. Schauffler, Portland, addressed a joint meeting of the Central Willamette Medical Society and the Polk-Yamhill-Marion Medical Society, October 7, at Corvallis on "Gynecology in Infants and Female Children."

PENNSYLVANIA

Health Centers Opened.—Six health centers for children from infancy to 6 years were recently opened in Schuylkill County by the Anti-Tuberculosis Society in cooperation with the state department of health. Examining physicians refer cases with handicaps to the family physician and send recommendations to the parents. The centers are open one day in the first week of each month.

Personal.—The forty-fourth annual dinner of the Association of Resident and Ex-Resident Physicians of the Philadelphia General Hospital will be held, December 2, at the Pennsylvania Hotel, Philadelphia. The dinner is in the form of a testimonial to Mr. George Taggart. Ex-interns are requested to notify the secretary, Dr. George Wilson, 133 South Thirty-Sixth Street, Philadelphia, of change of address.——At a regular meeting of the state board of medical education and licensure, November 13, at Harrisburg, Dr. Irvin D. Metzger, Pittsburgh, was elected president, and Charles D. Koch, deputy superintendent of public instruction, was elected secretary.

Society News.—The Berks County Medical Society was addressed, October 14, by Dr. Robert M. Alexander, Reading, on "Heart Disease from the General Practitioner's Standpoint."——Dr. Orlando H. Petty, Philadelphia, addressed the Blair County Medical Society, September 30, on "Obesity and Its Treatment."——A discussion of pernicious anemia formed the scientific part of the program of the Clarion County Medical Society in Knox, October 28.——Drs. Frank F. D. Reckord, Allen Z. Ritzman and Louis W. Wright, Harrisburg, conducted a symposium on pneumonia before the Dauphin County Medical Society, October 14.——Dr. Ralph H. Knapp, Youngsville, gave a summary from the recent literature on nephritis before the Warren County Medical Society, October 20, and Drs. William M. Cashman and Hamblen C. Eaton, Warren, spoke of the use of the new mercurials in relieving edema.——"The Relation of Posture to Pain and Visceroptosis" was the subject of Dr. John B. Carnett, Philadelphia, before the York County Medical Society recently.——Dr. Daniel Longaker, Philadelphia, addressed the Northampton County Medical Society, November 21, on "Conservative Obstetrics."

Philadelphia

Personal.—A bronze portrait bust of Louis Pasteur, through the will of Arthur C. Hugenschmidt, D.D.S., a friend of the famous scientist, who died in Paris last year, has been sent to the University of Pennsylvania. The bust was first placed on public view in the school of medicine, October 10, when a two-day celebration commemorating recent progress in medicine was opened. Dr. Hugenschmidt, dentist to Pasteur, was presented with the bust by Madame Pasteur after her husband's death.

Society News.—A symposium on clinical allergy was conducted before the Philadelphia County Medical Society, November 26; Dr. Arthur Fernandez Coca, New York, spoke on "Etiology, Symptomatology and Diagnosis of Allergic Disease"; Drs. James H. McKee, Martin E. Rehfuss, Harry P. Schenck and John H. Stokes took part in the discussion.——Dr. Louis D. Englerth, among others, addressed the Northern Medical Association of Philadelphia, November 17, on "The Treatment of Varicose Veins by the Injection Method."——[illegible] Society of Philadelphia was addressed, [illegible] others, by Drs. Isidor S. Ravdin and Charles G. Johnston on "The Absorption of Sodium Chloride from the Intact Gallbladder."——The West End Medical Society's program, November 19, consisted of a symposium on abdominal pain; the speakers were Drs. Joseph E. Kaplan, Samuel L. Immerman, Benjamin B. Rittenberg and Abraham Trasoff.

TEXAS

East Texas Healthcade.—A group of health workers, driving by automobile, recently spent five days covering 1,000 miles on a fixed itinerary, visiting forty-one towns, where they delivered 188 addresses to 18,000 listeners. The movement was inaugurated jointly by the director of the public health department of the East Texas Chamber of Commerce and the state department of health, headed by Dr. James C. Anderson, Austin, state health officer.

Changes at University of Texas.—Among the changes on the faculty of the University of Texas School of Medicine, Galveston, that were recently announced are: A. Lawrence Bennett appointed as associate professor of psychology, succeeding Philip L. Gray, resigned; Dr. William L. Marr, instructor in the practice of medicine, succeeding Dr. James A. Bradley, resigned; Dr. Harriss Williams transferred from experimental surgery to surgical pathology, and Dr. Robert M. Moore, appointed to succeed him.

Society News.—At a recent meeting of the Texas Association of Sanitarians, its name was changed to the Texas Public Health Association; Dr. Harry K. Read, Houston, was reelected president, and E. G. Eggert, sanitary engineer for the state department of health, reelected secretary.——The Texas Pediatric Society was addressed, October 28, in Fort Worth, among others, by Drs. Roy P. Forbes, Denver, on "Use of Catarrhal Vaccine in the Treatment of Respiratory Conditions"; William Weston, Columbia, S. C., "Foods That Do Not Nourish," and Josephine B. Neal, New York, "Encephalitis in Children."——The proceeds from the sale of "The Medicine Man in Texas," a history of the pioneer physicians of the state, of which the woman's auxiliary of the state medical association is sponsor, are to be used for a loan fund for the senior medical students at the University of Texas.——The Texas Interurban Club of Internists held a study week at the Mayo Clinic, Rochester, Minn., September 22-26. The program consisted of a series of lectures of vascular, renal and cardiac disease, medical seminars on gastro-enterology and other subjects, a conference on pathologic anatomy in relation to clinical observations, and symposiums on metabolic disorders and thyroid disease. Evening lectures were delivered by Drs. Frederick P. Moersch on "Multiple Sclerosis," and J. B. Doyle, "Encephalitis Epidemica."

GENERAL

Complimentary Copies of Biographic Sketches.—There are available for presentation by the author a number of copies of the *Biographical Sketches and Letters of T. Mitchell Prudden, M.D.*, by Lillian E. Prudden, which pupils of Dr. Prudden might be happy to have. If requests for the book are sent to *Miss Lillian E. Prudden, 424 Whitney Avenue, New Haven, Conn.*, they will be complied with as long as the presentation copies last.

Hygeia for School Teachers.—Two hundred and sixty-six subscriptions to *Hygeia* were recently secured by Dr. Earl F. Morris, director of health and physical education, Kansas State Teachers' College, Hays, Kan., to be sent to the student teachers in the college. Among other *Hygeia* subscriptions recently received are fifty-six from the woman's auxiliary of the Stark County Medical Society, Canton, Ohio, for teachers of that county. The principal of the Fair Oaks Public School, Fair Oaks, Ind., recently ordered twenty-one subscriptions to be sent to the schools in that community.

Dr. Williams Retires as Director of National Committee.—At the twenty-first anniversary meeting of the National Committee for Mental Hygiene, November 13-14, in New York, it was announced that the major objective in the committee's activities in the near future would be a nation-wide program of research in mental hygiene in cooperation with American universities. It will be carried on by Dr. Clarence M. Hincks, Toronto, Ont., the new general director who succeeds Dr. Frankwood E. Williams, New York, who, January 1, will retire after fourteen years of service. Dr. Hincks is founder and director of the Canadian National Committee for Mental Hygiene and vice president of the International Committee for Mental Hygiene. Dr. Charles F. Martin, Montreal, discussed the progress of mental hygiene work in Canada; Dr. Ralph A. Noble, Sidney, New South Wales, reviewed the work done in Australia, and Mr. Clifford W. Beers, founder and secretary of the National Committee and of the American Foundation for Mental Hygiene, outlined plans for international activities in mental hygiene work. Officers elected were honorary president, Dr. William H. Welch, Baltimore; president, Dr. Charles P. Emerson, Indianapolis, and secretary, Mr. Clifford W. Beers, New York.

Society News.—The next semiannual meeting of the Society for the Study of Asthma and Allied Conditions will be held in New York, December 6, at the New Yorker Hotel. This society is a limited organization, membership to which is by invitation only, to men who not only specialize in immunology but also have done real scientific work.——The Radiological Society of North America will hold its annual meeting in Los Angeles, December 1-5; among the speakers will be Drs. Emil G. Beck, Berkeley, whose subject will be "Cooperation Between Surgeon and Radiologist Essential to Effective Cancer Therapy"; Webster W. Belden, New York, "Further Observation of Osteitis Deformans"; Joseph C. Bloodgood, Baltimore, "Relative Merits of the Irregular Practitioner, Particularly in Relation to Cancer"; Carl H. Parker, Pasadena, Calif., "Treatment of Compressed and Impacted Fractures of the Bodies of the Vertebrae"; William Edward Chamberlain, San Francisco, "Bone and Joint Changes of Leprosy"; Robert S. Stone, San Francisco, "X-Ray Findings in the Chests of Tuberculin-Positive Children," and Harry M. Weber, Rochester, Minn., "Roentgenologic Manifestations of Tuberculosis in the Alimentary Tract," and Jesse W. M. Du Mond, Ph.D., and Archer Hoyt, Ph.D., Pasadena, "Present Status of the Problem of Measurement of X-Ray Intensity and Quality."——On call of the surgeon general of the U. S. Public Health Service, a conference of health and welfare workers was held in Washington, D. C., October 29, to consider ways and means of controlling the high mortality of colored people in rural communities and congested cities. The committee was formed to consider the year-round health movement with Dr. George W. Bowles, York, Pa., chairman. Plans are made for observance for the next Negro health week, which includes the birth date of Booker Washington, April 5.——"Undulant Fever from a Physician's Standpoint" and "Newer Aspects of the Prevention of Tuberculosis" will be the subjects of Drs. Richard A. Kern, Philadelphia, and Jay A. Myers, Minneapolis, before the thirty-fourth annual meeting of the United States Live Stock Sanitary Association, December 3-5, in Chicago.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 8, 1930.

The Public Health

In his annual report for 1929, Sir George Newman, chief medical officer of the ministry of health, again calls attention to the falling birth rate. The natural increase of population by births over deaths is now less than half what it was so recently as the period 1921-1925. The principal causes of death per thousand deaths were: diseases of the heart and circulation, 225; respiratory diseases, 157; cancer, 107; diseases of the nervous system, 82; tuberculosis, 71. There was lost to the insured population alone by sickness or disablement 29½ million weeks' work. A large section of the report is devoted to maternal mortality, which is lower in London than in any other part of the country, both for puerperal fever and for other causes, and high in the industrial North and in Wales. Where the maternal mortality is high the infant mortality also tends to be excessive. Effective antenatal supervision of every case of pregnancy is declared to be needful and there is also a need for improved obstetric practice.

BIRTH CONTROL

Considerable space is devoted to birth control. It is laid down that organized instruction in contraceptive methods is foreign to the purpose of a maternity and child welfare center established by a local authority for nursing and expectant mothers, would militate against the object of its establishment, and might well be alien to its clients. But "in exceptional circumstances, when avoidance of pregnancy seems desirable on medical grounds, the mother attending the center should be referred for advice as to birth restriction to a private practitioner attached to or recommended by the center, or to a suitable hospital or clinic. It is pointed out that birth control is not a novel idea but has existed from the earliest times. The only change is that it has become more conscious, concrete and talked about, and more artificial in method. The change was not necessarily evil nor did it raise new moral issues. It has brought definite relief to a large number of persons from immediate difficulties. However, its indiscriminate advocacy has had many disadvantages. Organized public instruction is liable to become propagandist and pseudo-authoritative and to lead to commercial exploitation. The effects may be not only local and physical, but general, organic, psychologic and even antisocial. The means may be deleterious in their results and are in any case uncertain in their action. There is no guarantee of value, physical, moral or humane. Birth control cannot be, in any case, a substitute for social amelioration, self-control, restraint or mutual consideration. It is doubtful whether there is sufficient unanimity in the medical profession or in public opinion as to contraceptive methods to justify a local authority supporting out of the taxes a center for systematic instruction.

THE INSURANCE MEDICAL SERVICE

The number of insurance practitioners in England and Wales was 15,573 and the average number of insured on one man's list was 932; 44 per cent of men physicians and 33 per cent of women are engaged in insurance practice. As to efficiency, it is declared that patients as a rule are considerate to their physicians and do not make unnecessary demands, and the physicians do their best for patients. But there are of course exceptions to both rules.

THE INCREASED SICKNESS CLAIMS

It has been shown in previous letters that excessive sickness claims are inherent in such a form of medical socialism as the insurance system, which, while excellent from the point of view of insuring persons against sickness who would be unable to pay for it in the ordinary manner, is not so in throwing the greater part of the cost on others, who derive no benefit from the system. There was a further increase in the number of sickness claims in 1929, which led to investigations. A scrutiny was made of a large sample of those cases which were referred from the insurance practitioner to the "regional medical officer" by the lodges when they doubted the claim. Many of these persons concerned avoided coming for examination by ceasing to draw benefits. The proportion was found highest in married women of 45 and under; single women came next, and both of these were much higher than the men or the married women of 46 and over. The large proportion of persons who ceased to draw benefit when referred after a short period of incapacity for some trivial cause, set out as catarrh, chill, cold, influenza or neuralgia, is noteworthy. It is admitted that in many of these cases a final certificate would have been given if the patient had not been referred. But it is stated that "when full allowance has been made for this, it is difficult to resist the conclusion that in many of these cases a final certificate ought to have been issued at an earlier date." The societies may be compelled for the protection of their funds to refer cases of this type at a much earlier stage of illness.

A RECORD CANCER DEATH RATE: "CANCER CURERS"

As the figures show, cancer is now the third of the great killing diseases. The number of deaths from cancer amounted to 56,896, which was 1,437 per million of population, the highest ever recorded, and 10 per cent of the total number of deaths. The rate has doubled since 1890 and trebled since 1870, and more than quadrupled since 1850. A curious change has taken place in the sex incidence. The susceptibility of females in 1851-1855 was more than double that of males, but in 1921-1925 the two sexes were approximately level and in the last few years the susceptibility of males has apparently been the greater. When a cancer "cure" is brought to the notice of the cancer committee of the ministry of health, information is asked as to the nature and composition of the remedy, authentic records of proved cases of success, and evidence that it is not harmful. It is found that the professed "cancer curer" is rather reserved in the presence of this investigation. It is admitted that he may cure some superficial cancer by caustics, but this action is well known to the medical profession and it is also known that removal can be effected more quickly and usually more painlessly and with less disfigurement by surgery. Charlatanry more often than ignorance seems to be the trouble with the cancer curer. He trades on the facts that some cancers are difficult to diagnose, that his preparations sometimes lead to healing of the local disease, and that, on the part of the public, fear of the disease, ignorance and the secrecy with which the treatment is enshrouded combine to make people ready victims.

The Liquor Problem in Great Britain

Further important information on the drink question is furnished by a government blue book just published. Jan. 1, 1929, there were in England and Wales 78,307 saloons licensed for the sale of intoxicants for consumption on or off the premises and 22,171 for consumption off the premises, giving a proportion of 19.7 on-licenses and 5.6 off-licenses per 10,000 of population. In the decade 1895-1904 there was an average annual decrease of on-licenses of 486 and in the twenty-four years 1905-1928 of 882. Jan. 1, 1908, there was 1 on-license for every 367 persons; Jan. 1, 1929, only 1 for every 506. The number of convictions for drunkenness in 1929 was 51,966, against 55,642 for 1928, and was the lowest in any years since 1918. The cases in which the person convicted of drunkenness is reported to have taken methylated spirit decreased from 446 in 1928 to 409. Thus the great improvement in the habits of people with regard to indulgence in alcoholic drinks, which has been in progress for some generations, continues.

Eyesight Tests for Automobile Drivers

Under the new road traffic bill the following question was drafted to be put to applicants for a driving license: "Is your power of distant vision in one eye at least (with glasses if worn) not less than 50 per cent of normal?" After consultations between the minister of transport and the British Medical Association, the eyesight requirement was altered. The question now reads: "Are you able to read at a distance of 25 yards in good daylight (with glasses if worn) an automobile car plate containing six letters and figures?" In the opinion of the British Medical Association, any one who cannot bring his vision up to this standard with glasses cannot be regarded as a safe driver of an automobile. The second disability that will be regarded as an absolute bar to obtaining a driver's license is epilepsy or liability to sudden attacks of disabling giddiness or fainting.

Postoperative Accidents in Cerebral Surgery

In an article in the *Presse médicale*, Dr. T. de Martel has reported the results of his wide experience with cerebral surgery and has described the nature and treatment of the accidents that may occur after the removal of brain tumors. In his opinion, such accidents are due to circulatory disturbances of the cerebrospinal fluid. The extravasated blood may clog the points of communication between the cavities in which the fluid circulates. There results an intraventricular hypertension, which distends the cavities of the ventricles and brings about an anemia of the compressed peripheral cerebral tissue. Under this pressure, the lower portions of the brain tend to protrude through the occipital opening. The upper centers are attacked first, which becomes manifest through loss of consciousness and coma; then the vegetative centers, the respiratory centers, and the heat regulatory centers are attacked. The patient dies in hyperthermia, with respiratory syncope. The treatment for these accidents was described by de Martel explicitly. The hyperthermia must be combated, it being of a physiologic nature and not infectious, by cold compresses and repeated intestinal irrigations with cold water. A lumbar puncture is done, or, better still, a cistern puncture, to be repeated until the fluid that emerges is clear. If the intraventricular hypertension recurs nevertheless, an intraventricular puncture should be done without delay. Finally, also intravenous injections of a 15 per cent hypertonic solution of magnesium sulphate render excellent service by diminishing, through osmosis, the amount of cerebrospinal fluid and the cerebral edema that sometimes follows the operative act, especially if performed with the electrical knife. Injections of epinephrine are useful when a lowering of arterial tension is associated with the hyperthermia. All these maneuvers when indicated necessitate prompt action, which requires every patient who has undergone a brain operation to be kept under constant supervision and in charge of extremely competent personnel.

Use of Ultraviolet Rays for the Destruction of Harmful Insects

An apparatus invented by Mr. Gourdin, and already in use in France and in Greece, utilizes ultraviolet rays to attract and to destroy nocturnal insects that cause harm to man and to agriculture. The apparatus is a sort of beacon, supplied with a mercury vapor lamp, which attracts insects and captures them in a reservoir trap. During an experiment carried out in the vicinity of Montpellier on a clear night, 545,073 insects were captured within two hours, of which 513,000 were anopheles mosquitoes, 3,200 cochylis and 12,000 butterflies. Further experiments, no less conclusive, have been carried out in Corsica, Algeria and Italy. The Société des viticulteurs of France, in recognition of the protection given to vineyards by the destruction of the insects that tend to destroy them, has bestowed a medal on the inventor. Great importance is attached to this invention for the prophylaxis of malaria.

Employment Bureau for Students

The cost of higher education and of living in general has created in Paris a situation that is exceedingly unpleasant for students of limited means. Many students find it necessary to eke out their slender income by serving, in the evening, as taxicab drivers or in other capacities. An employment bureau has been established by the Association des étudiants at its headquarters, 13 rue de la Bucherie, under the name of Office des travailleurs intellectuels, with a view to procuring for its members part-time work. A new occupation has been opened up to them through the initiative of the directors of theaters and motion picture houses: that of *placeur*, or usher. Heretofore the ushering has been done by women. It requires only a pleasant manner and a little dexterity of movement. The women who serve in that capacity are usually of the indolent sort. Often, when not busy, they stand about the corridors and converse among themselves, to the disturbance of the audience. The innovation has been welcomed by the public, which shows its sympathy for these courageous young men by giving them large tips. During the intermissions, they devote themselves to their books, which they bring with them and the audience is no longer disturbed by chattering in the corridors. The press has contained a number of articles on the subject. Feminine sympathizers complain because an easy source of revenue has been taken away from women who in this way were supplementing their otherwise meager incomes. In the main, the innovation is approved by the public. It is well for the public to know that an intellectual career often requires great sacrifice and that the professions are overcrowded because they attract too many young men—far beyond the needs of the country.

Ceremonies Honoring Ambroise Paré

The Academy of Medicine devoted a recent session to honoring the memory of Ambroise Paré, the "father of French surgery." Prof. Jean-Louis Faure was selected to deliver the memorial address. In the beginning of his career, Paré was an ordinary "barber," being authorized only to shave the beard, to cut the hair and to practice bleeding according to the recognized indications of that period (1509-1590). Later, he became attached for two years as assistant to the Hôtel-Dieu de Paris, and it was there that he saw operations performed according to the customs of his time, which included the use of the cautery and dressings of boiling oil, which accomplished a veritable antisepsis, though in a cruel fashion. Paré was the first to apply arterial ligatures in amputations, in opposition to the belief of Hippocrates that it is best to allow wounds to bleed to prevent inflammatory congestion. He was the surgeon of Francis I, Henry II, Charles IX, Henry III and Henry IV. He died at the age of 80. During the massacre of the Huguenots and the sad days of St. Bartholomew, Charles IX protected him, although he was a Protestant, by concealing him, at the Louvre, in his own apartment. He had considerable trouble in securing the diploma of the Royal College of Surgeons, as one of the requirements for a candidate was that he should defend his graduation thesis in Latin, a language with which he was not on the best of terms. He succeeded in getting his diploma only through the intervention of the king. In spite of this, his keenness of observation, his inventive genius, his manual dexterity and his unimpeachable professional honor won for him the title that posterity has bestowed on him for more than three centuries and caused him to be lifted up as the model of a surgeon.

Death of French Physiologist Gley

Dr. Emile Gley, an eminent French physiologist, died recently in Paris. Born at Epinal, in 1857, after pursuing his studies in the Facultés de médecine de Montpellier and de Nancy, in the Facultés des Lettres de Nancy and de Paris, in the Collège de France, and in the laboratoire de Marey, secured the diplomas of doctor of medicine and licencié-ès-lettres. Gley was awarded on several occasions the title of "laureate" of the Academy of Medicine and of the Academy of Sciences. Former agrégé professor of the Faculté de médecine de Paris, he became later occupant of the chair of general biology in the Collège de France. He was likewise the correspondent of various foreign academies. His researches embraced a broad field of physiology (functioning of the heart, coagulation of the blood, innervation of the lymph vessels, antitoxin function of the liver, functions of the thyroid gland and of the parathyroid glands, rôle of the suprarenal glands, internal secretions). He was a former president of the Academy of Medicine. Last July, the Institut de France bestowed on him one of the Osiris prizes. He was the author of "A Treatise on Physiology," which has remained a classic.

TURKEY

(From Our Regular Correspondent)

Ankara, Oct. 30, 1930.

Third National Medical Congress

The third national medical congress was held, September 17-19. Ismet Pasha, the prime minister, in the opening address mentioned that the maximum number of students had been admitted to the medical school this year, but there still would be in the future a scarcity of physicians and it would be necessary to arrange for another medical center. The minister of health and social assistance, Prof. Dr. Refik Bey, presided. The foremost subjects for discussion were syphilis, cancer and scarlet fever. Drs. O. Sherefeddin and A. Shukri reported on the biology of syphilis and on syphilis laboratories, Drs. H. Reshad, H. Behdjet and F. Kerim on the clinical aspects of syphilis, and Dr. Talat on the treatment of syphilis. Drs. Hamdi Suat, Saim Ali and Lutfi reported on cancrology, Drs. A. Kemal and Burhaneddin on the surgical treatment of cancer, and Drs. S. Mehmed and T. Remzi on radium treatment of cancer. Drs. Server Kiamil and Hasan Vasif reported on scarlet fever. The congress was open to miscellaneous subjects, among which were roentgen treatment of asthma, cancer and the pathologic laboratory, syphilis of the stomach, malaria treatment of syphilis of the nervous system, the treatment of tetanus, the relation of race to cancer, cancer in Turkey, cancer of the upper respiratory tract, relation of cancer and syphilis, rachitis from the social point of view, smallpox vaccine and its subcutaneous application, scarlet fever studies of the ministry of health, bone tumors and the value of roentgen diagnosis, Wassermann reaction in advanced age, syphilis and bismuth, measures against the practice of abortion, proprietary medicines of Turkish origin, an uncommon form of encephalitis, frontal sinus coccidiosis of the right eye, measurement of intensity of natural ultraviolet rays in Turkey, and observations from the mental hygiene point of view.

In order to provide meetings and to further surgical publications it was decided that the surgeons organize a Turkish surgical society.

The 1,500 pages of reports have been distributed to each of the 500 congress members who then had an opportunity to visit the exposition which had been arranged in connection with the congress. Here proprietary medicines, medical and surgical instruments of Turkish and foreign origin, together with casts of the hygiene museum, health posters, health propaganda publications and diagrams of the ministry of health were on exhibition. The collections in connection with the development of vegetable, animal and human cancer as related to the discussions exhibited by Prof. Dr. Hamdi of the pathologic laboratory of the medical faculty proved to be of great interest.

The next congress is to be held in 1931 again in Ankara. The minister of health, Prof. Dr. Refik Bey, has been reelected president. The chief topics for discussion are to be the questions of nutrition in urban and rural communities, infant and child nutrition, and rachitis.

Children Excluded from the Cinema

Until now there has been no special law in Turkey excluding children from motion picture houses. At all performances, small children and even infants can be observed in such places. Often the young mother has no reliable person at home with whom to leave the child, and the young woman of the present day is much interested in the cinema. She is now at liberty to go pretty much were she pleases. For the reason that among the poor classes the old custom of going everywhere *en famille* is still adhered to, it is no rare occurrence for the audience at the height of a performance to be disturbed by the wails of nurslings.

Diseases of the respiratory tract and infectious disease in children can often be traced to the fact that the children have been taken to the cinema, where they have sometimes remained for hours and where overcrowding, smoke and vitiated air are so often prevalent.

Article 164 of the new public health law, which goes into effect November 6, makes it prohibitive for children under 6 years to be taken to the cinema. Children from 6 to 12 years may visit the cinema until 8 p. m. Exhibitors are obliged to put up notices in large letters and in conspicuous places. Children found in cinemas contrary to the provisions of the law will, if necessary, be forcibly removed and their parents or wards as well as the cinema proprietors fined in order to safeguard the health of growing children.

The Child Care Department of the Istanbul Asylum

As the new municipal law provides for certain regulations in regard to child welfare work, the municipality of Istanbul has prepared a program in which the first step is to broaden the activities of the Istanbul asylum for the old and infirm, where deserted infants are cared for also. In the future, preschool children in need of state protection are to be received there. Arrangements are to be made for good physical care and also for the mental development of these children.

BERLIN

(From Our Regular Correspondent)

Nov. 3, 1930.

The Importance of Psychic Processes

In an article in the *Deutsche medizinische Wochenschrift*, Prof. G. von Bergmann of Berlin emphasizes the importance of the psychic for the treatment of the physical. While a few physicians of the old régime (for instance, Hufeland, in his "Makrobiotik") recognized the influence of emotions on the bodily functions, more precise research on the subject was not done until recent years, especially since the Russian psychologist Pavlov established by his famous experiment on dogs the existence and the mode of origin of a psychically induced secretion of gastric juice. It has been shown by hypnotic experiments on man that the mere suggestion that a fine meal is spread before one may stimulate the secretion of the gastric juice. If one looks through a "celluloid window" set experimentally in the abdomen of a rabbit, it may be observed that an active movement of the whole intestinal canal begins when a turnip is shown to the hungry animal. If, however, the ear of the rabbit is then pinched, under the influence of the pain the intestinal movements will quiet down and the intestine will become pale. At the mere suggestion of physical work that is to be done with the right arm, the right arm becomes heavier owing to the influx of a greater blood supply. These remarkable facts attracted attention before they were understood. As far back as 1834, Beaumont reported observations on Alexis St. Martin, who had a stomach fistula through which one could observe that, when the subject was influenced by fear or anger, the gastric walls became red and dry and lost their shiny appearance, while the gastric secretion was diminished. Some time ago, a man was presented at clinical lectures who gave evidence of a chill, accompanied by trembling and goose-flesh, when he caught sight of the physician in his white overgarment standing near him, suffering from the delusion that the physician was a snow man and that he himself was standing nude out in the cold. Many such illustrations of the influence of the mind on the body can be given. Such connections are, however, much more subtle than is commonly supposed. The approach of a sick spell is heralded often by a change of mood and of disposition. We are irritable, low spirited and "nervous." The "cold" or the sore throat does not appear until the day following. Certain contagious disorders or mild poisonings are, according to the observations of Bergmann, more easily recognizable by observation of psychic behavior than by the study of clinical symptoms, which fact should be utilized more than it is for the diagnosis. "There are for the physician," he writes, "a great number of observations through which the subtle subjective perception of the patient will furnish important points of evidence, whereas the much coarser objective observations fail completely to accomplish the purpose; for instance, fatigue, weakness of memory, absentmindedness and mental excitement are often subtle indicators when it is impossible to recognize a poison by chemical means, a cell injury through an anatomic examination or a disturbed functioning as an objectively discoverable manifestation. Therefore, the subjective complaint of the patient often becomes for the internist the most important, and, not infrequently, the only evidence of illness." These foreshadowings of sickness may consist of an exalted mood and increased activity; for example, in alcoholic intoxication or following an injection of morphine. Another example: A senior student in the "gymnasium" is happy over the fact that he no longer needs to resort to strong coffee in order to keep awake. His drowsiness has disappeared, and he memorizes his odes from Horace with great ease, whereas previously it required great effort. A few days later he dies from epidemic encephalitis. The increased memorizing capacity was only a foreshadowing of a grave brain disorder. The study of personal character is an inherent part of the study of the constitution, and it is important for the physician to know how his patient "steps" in both a literal and a figurative sense of the word; how he shakes hands; how the most delicate motions are revealed as graphic strokes in the handwriting; in short, even how he clears his throat and expectorates. From the study of the physical bases of psychic moods, certain conditions may be more accurately understood; for instance, the idea of convalescence. So long as all that was known was that the patient was no longer ill but was not yet well either, the physician had to be content with such complaints during convalescence as: "I am tired, weary, have no desire to work." Now, however, it has been shown that, for weeks after a sore throat or pneumonia, when temperature, blood picture and other reactions have long become normal, the cell composition of a blister produced artificially on the skin is still abnormal; that is, it still presents a changed behavior in the organism. Thus a biologic explanation is available for the proverbial irritable mood of the convalescent patient.

Lead Poisoning from Tap Water

Lead poisoning from the drinking water has caused considerable anxiety in Leipzig. Professor Kruse and Dr. M. Fischer, who are connected with the Hygienisches Institut at the University of Leipzig, made a thorough investigation of the regrettable occurrence and have published a preliminary report of their conclusions, in the *Deutsche medizinische Wochenschrift*. Thus far, about 250 patients have received treatment, and it has been established that only persons who have a predisposition for lead poisoning become ill from the ingestion of lead with the drinking water. The water contains considerable lead not only after standing a long time in the water pipes but often after it has been in the pipes from one to four hours, so that water drawn from the pipes during the day may be dangerous if one does not allow it to run for a short time before using it. The water in the section of the city in which the cases of poisoning occurred was found to contain much larger quantities of lead than ordinary tap water has. The quantity ranged between 2 and 25.6 mg., the average being about 5.3 mg. The water is derived from two sources, recently reorganized. The present water supply in Leipzig attacks lead pipes much more intensely than the former supply, and the new lead pipes, from the standpoint of durability, do not stand up as well as those formerly employed. While the reasons for the recent epidemic of lead poisoning are not yet entirely cleared up, the assumption appears justified that the unfortunate event can be explained only by the coincidence of numerous factors difficult to weigh. The residents of the section of the city in question are able to protect themselves at present only by drawing off one or two pailfuls of water before beginning to use it. A further reorganization of the water system is, however, in progress and will be completed shortly whereby the whole water supply of Leipzig will be neutralized by solution of calcium hydroxide, thus removing all danger from lead poisoning from tap water.

The Determination of Blood Groups and the Courts

The Württemberg ministry of justice calls attention to the fact that, in cases involving fatherhood and maintenance obligation, the courts, not infrequently, put the child's mother under oath as to her testimony and then enter an order for an examination of blood groups. To prevent perjury, the courts are now advised in such cases to reverse the order and to proceed first with the determination of the blood groups and then, if necessary, to place the child's mother under oath. In this manner, by holding before the witness the results of the blood group determination, one can frequently prevent statements being sworn to that do not harmonize with those results. This order of procedure is in accordance with the trend that is becoming more and more evident in the prosecution of justice in the German courts whereby, through more skilful handling of the taking of evidence, perjury may be prevented.

Continuation of the International Hygienic Exposition in Dresden

It had been the intention to close the Internationale Hygiene-Ausstellung Dresden, October 12. In spite of bad weather, which cut down the attendance, nearly three million persons visited the exposition. But, in order to score the success in Germany and in foreign countries to which the exposition is entitled, a much greater attendance is needed. A large number of investigating commissions have visited the exposition. Since, in 1931, few, if any, large expositions are announced for Germany next year, the Dresden exposition will be opened again in 1931. The famous exhibit of modern hospitals and their equipment will be preserved complete. Many of the set-ups will be reorganized, and other set-ups entirely new will be added. Also the foreign exhibit, which is housed in the Staatenhaus, will be enriched by the addition of material, much of which, owing to the short time allowed for the preparation of the exposition of 1930, could not be assembled. Considerable material from America has already been promised. Another new set-up will be a general survey of Catholic missionary enterprises in foreign countries. It is the intention of the committee to secure a large attendance of the public. A special and regular train service from all parts of Germany and from many points in foreign countries will therefore be organized.

Seventieth Anniversary of Berlin Medical Society

October 29, the Berliner Medizinische Gesellschaft convened in special assembly in honor of the seventieth anniversary of its existence. The society arose in 1860 through the merger of two older societies, under the chairmanship of the founder of modern ophthalmology, Albrecht v. Graefe. The chairmanship then passed to the director of the Chirurgische Universitätsklinik, Bernhard v. Langenbeck; then to Rudolf Virchow; Ernst v. Bergmann, surgeon: Senator, internal clinician; Orth, pathologic anatomist, and Kraus, internist. Since its foundation, the society has been the scientific center of the medical profession of Berlin. The transactions of the Berliner Medizinische Gesellschaft receive widespread attention throughout Germany and are noted in foreign countries. The present chairman, Geheimrat Goldscheider, gave, in his address, a survey of the development of the art of healing during the past seventy years as reflected in the activities of the society, and then digressed to the present reduced economic status of physicians. After the secretary, Professor Adam, had given a survey of the history of the society, Prof. Martin Hahn, hygienist at the University of Berlin, delivered an address on "Hygiene of a Metropolis." He brought out that the mortality in the large cities, as far as acute infectious diseases are concerned, is not higher than in the country as a whole. One of the most difficult problems in the hygiene of large cities is the increased mortality of men of the 30 to 70 age groups, in contrast with the mortality of women of the corresponding ages. This greater mortality of men in these years of full earning capacity is doubtless due chiefly to alcoholism, tuberculosis, venereal diseases and occupational injuries. If we are to continue to compensate for the decline in the birth rate by reducing the mortality in the large cities, we must not stop with the combating of acute infectious diseases but must attach equal importance to the fight against the chronic injuries of metropolitan life, which is, to be sure, even more difficult. The first step in this direction is the improvement of housing conditions. The provision of an adequate supply of water for metropolitan areas is becoming an increasingly difficult problem. Since the large volume of water taken constantly from the Spree area, near Berlin, is gradually impairing navigation, and the lowering of the water level of the Spree leads to contamination of its waters, a collection of the water in the lakes of the Spree forest or the installation of a powerful pumping plant on the banks of the Oder will soon become necessary, to maintain Berlin's water supply. The demand for water, caused by the growth of industries, the increase in the number of private bathrooms and the more widespread use of hot water installations with the accompanying waste of water, has led naturally to an increase in the amount of refuse water, which can no longer be deposited on the fields adjacent to Berlin. For that reason, Berlin is constructing a large purification plant.

It would be well for the youth of the large cities if the many school reforms were not tried out on them, for they are already inclined to be precocious. Also the numerous diversions and stimulations in the form of field excursions, lectures, motion pictures, "shows," theatricals, journeys even to foreign countries, offered to children nowadays go beyond their needs, since they are naturally mentally active and inclined to be somewhat "nervous." What they need for a healthy mental and physical development is more concentration and better opportunities to participate in family life.

In closing, Hahn emphasized that an annual voluntary examination of supposedly healthy persons would contribute greatly toward the early recognition of chronic injuries incident to the life of a large city and would tend to preserve the sense of responsibility that still remains after the decline of recent years.

Who Should Hold the Title of "Professor"?

The executive committee of the Verband der Krankenhausärzte Deutschlands (league of hospital physicians of Germany) took up recently with the Prussian minister of public welfare the subject of the bestowal of the title of "professor" on physicians who are directors of hospitals and brought out that the term "professor" should be applied only to such persons as hold an official teaching position. That principle is widely neglected, even by the government itself. Since the title of "professor" in the mind of the people is supposed to evidence more than ordinary scientific qualifications, many eminent hospital directors who did not attain their post by way of a university career suffer a hardship both from the ideal and from the economic point of view. Many hospital directors who are not connected with any particular institution of learning are employed by the state for the training of medical practitioners and for the holding of graduate courses. The league requested, therefore, that the title of "professor" be bestowed again on hospital physicians with suitable scientific attainments. Under date of August 15, the Prussian minister of public welfare replied that he had frequently taken the stand that the service title of "professor" should be given physicians who are directors of hospitals but that, in view of the present wording of the constitution, there was no way in which that objective could be reached.

Capillaries and Physiognomy

Professor Bettmann, dermatologist, presented recently to the Heidelberg Academy of Sciences the results of his researches on the relations of the capillary forms of the lip to the physiognomy. According to his observations, the type of the capillaries of the lower lip has a direct relation to rest and forms of motion, tension and release of tension, types of development, age, sex, constitution; condition of the teeth, jaws, facial muscles, muscles of mastication; speech, tone and play of the features. The physiognomy is strongly influenced by the mucous membrane of the lip. The type of the capillaries is simple, scant and defective in primitive races in which play of the features is wanting; also in mental patients, and in aged persons it is more complex and more fully developed in actors, elocutionists, mimics, professional whistlers and players of wind instruments.

Anniversary of Society for Promotion of Graduate Instruction

The Dozentenvereinigung für ärztliche Fortbildungskurse of Berlin celebrated, October 16, its fiftieth anniversary. By providing opportunities for graduate instruction in medicine the society has contributed to the uplift of public health, and by attracting to Berlin at least an equal number of foreign physicians it has increased the prestige and the scope of the knowledge of German scientists. The society has always been ready to assume the task of cultivating personal relations between foreign and German physicians. The ceremonies, held in the Kaiserin-Friedrich-Haus, were opened with an address by Prof. Dr. Munk, the chairman of the society. Professor Adam, director of the Kaiserin-Friedrich-Haus, gave a survey of the history of the society.

Marriages

William Andrew Brumfield, Jr., Staten Island, N. Y., to Miss Elizabeth Mitchell Fagg of Blacksburg, Va., October 7.

Douglas Fairbanks Love, New Market, Va., to Miss Dorothy Anne Settle of Amherst, October 16.

Patrick Henry Winston, Virgilina, Va., to Miss Lillian Frances Gayle of Stafford County, October 8.

Charles Henry Henderson, Richmond, Va., to Miss Mary Virginia Chiles, Fredericksburg, October 1.

William Nash Thompson, Stuart, Va., to Miss Opal Norene Ingram, in Danville, October 6.

Irvine Heinly Page to Miss Beatrice Delamater Allen, both of Melrose, Mass., October 28.

John I. Chorlog, Madison, Wis., to Miss Hazel I. Sheets of Clifton Forge, Va., recently.

Rufus Marion DeHart, Floyd, Va., to Miss Rachel Bass of Richmond, October 21.

Deaths

William Mulholland Beach ⊕ Pittsburgh; Jefferson Medical College of Philadelphia, 1889; member of the American College of Surgeons; chairman of the Section on Gastro-Enterology and Proctology, American Medical Association, 1918-1919; lecturer on anatomy at the University of Pittsburgh, 1889-1892; past president and secretary of the American Proctologic Society; an organizer and for many years on the staff of the Presbyterian Hospital; on the staff of the Southside Hospital, 1906-1911; member of the board of trustees of the Waynesburg (Pa.) College; aged 71; died, October 23, of bronchopneumonia.

Junius Clarkson Hoag, Chicago; Chicago Medical College, 1882; member of the Illinois State Medical Society; member of the American College of Surgeons; at one time instructor and demonstrator of obstetrics at his alma mater; past president, vice president and secretary of the Chicago Medical Society; on the staffs of St. Luke's Hospital, Mercy Hospital and the Provident Hospital; aged 72; died, October 25, of carcinoma of the ascending colon.

Archibald Neil Sinclair ⊕ Honolulu, Hawaii; University of Glasgow Medical Faculty, Glasgow, Scotland, 1894; member of the American College of Physicians and the Society of American Bacteriologists; past president of the Territorial Board of Medical Examiners, and the Hawaii Territorial Medical Society; medical director of the Leahi Home; aged 59; died, October 21, of heart disease.

Andrew Bartholomew Somers, Omaha; Medical Department of Columbia College, New York, 1872; member of the Nebraska State Medical Association; professor emeritus of obstetrics, University of Nebraska College of Medicine; past president of the Omaha-Douglas County Medical Society; formerly member of the state board of health; aged 83; died, October 23, of uremia.

Joseph Calvin Reifsnyder ⊕ Scranton, Pa.; Jefferson Medical College of Philadelphia, 1888; veteran of the Spanish-American War; past president of the Lackawanna County Medical Society and the Pennsylvania Public Health Association; county medical director; on the staff of the Lackawanna County Tuberculosis Hospital; aged 62; died, October 23, of heart disease.

Charles Evart Paddock ⊕ Chicago; Chicago Medical College, 1891; formerly assistant professor of obstetrics, Rush Medical College, and professor of obstetrics, American Medical Missionary College; member of the American College of Surgeons; aged 71; on the staff of St. Luke's Hospital, where he died, November 1, of heart disease.

Christopher J. Woolway, Duluth, Minn.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1875; formerly superintendent of the St. Louis County Almshouse and Tuberculosis Pavilion, and the Deerwood (Minn.) Sanatorium; aged 76; died, October 28, in a local hospital, of angina pectoris, chronic endocarditis and gastritis.

Joseph Seal Neff, Narberth, Pa.; Jefferson Medical College of Philadelphia, 1875; director of the department of public health and charities, 1907-1914; attending physician to the Philadelphia General Hospital, 1882-1889; director of the Jefferson Medical College Hospital, 1893-1907; aged 76; died, November 4, of heart disease.

James Alexander Anderson, Smiths Falls, Ont., Canada; Trinity Medical College, 1903; served during the World War; formerly member and chairman of the board of education, member of the board of health and mayor of Smiths Falls; on the staffs of the Public and St. Francis hospitals; aged 60; died, August 4, in Toronto.

Mary Vincent O'Callaghan, Worcester, Mass.; Woman's Medical College of Pennsylvania, Philadelphia, 1885; member of the Massachusetts Medical Society; on the staff of St. Vincent Hospital; aged 78; died, October 28, in the City Hospital, of injuries received when she was struck by an automobile.

William Ford Blake, San Francisco; Cooper Medical College, San Francisco, 1903; member of the California Medical Association, the American Academy of Ophthalmology and Oto-Laryngology and the American College of Surgeons; aged 57; died, August 28, in Palo Alto, of chronic nephritis.

Robert W. Stewart, New York; Medical College of Ohio, Cincinnati, 1882; at one time professor of clinical obstetrics, Miami Medical College, Cincinnati; formerly on the staff of the Jewish Hospital, Cincinnati; aged 76; died, November 1, of arteriosclerosis and acute dilatation of the heart.

Charles Bledsoe Crute, Farmville, Va.; University of the South Medical Department, Sewanee, 1903; member of the Medical Society of Virginia; served during the World War; aged 50; died, October 9, in the Memorial Hospital, Richmond, of injuries received in an automobile accident.

John Alfred Jackson, Los Angeles; Trinity Medical College, Toronto, Ont., Canada, 1897; member of the California Medical Association, and the Associated Anesthetists of the United States and Canada; on the staff of the Los Angeles County Hospital; aged 62; died, August 26.

James Lawrence Maupin, Fresno, Calif.; St. Louis College of Physicians and Surgeons, 1890; member of the California Medical Association, and the State Board of Medical Examiners; on the staff of the Burnett Sanitarium; aged 62; died, October 1, of cerebral hemorrhage.

Allen Mason King, Jacksonville, Ill.; Barnes Medical College, St. Louis, 1902; member of the Illinois State Medical Society; served during the World War; aged 54; on the staff of the Passavant Memorial Hospital, where he died, September 21, of pneumonia.

John Henry Coughlin ⊕ New York; Medical Department of the University of the City of New York, 1889; formerly clinical professor of medicine, Fordham University School of Medicine; on the staff of the Gouvernour Hospital; aged 76; died, October 19, in Atlantic City, N. J.

Philip Patrick Moore, Gloucester, Mass.; Harvard University Medical School, Boston, 1899; member of the Massachusetts Medical Society; formerly city physician, school physician and chairman of the board of health; aged 65; died, in October.

Arthur E. Prince ⊕ Springfield, Ill.; Medical Department of the University of the City of New York, 1877; medical superintendent of the David Prince Sanitarium; aged 76; died, October 21, of pulmonary carcinoma and acute parenchymatous nephritis.

Frank V. Winstead, Dixon, Ky.; University of Louisville School of Medicine, 1892; member of the Kentucky State Medical Association; aged 62; died, October 12, in the Walker Hospital, Evansville, of injuries received in an automobile accident.

David Currie Ross, San Diego, Calif.; Dallas (Texas) Medical College, 1903; Chicago Hospital College of Medicine, 1914; aged 57; died, September 3, of pneumonia and traumatic pyemia, as the result of injuries received in an automobile accident.

Samuel J. Hunkin ⊕ San Francisco; University of California Medical School, 1890; at one time professor of orthopedic surgery, Oakland College of Medicine and Surgery; formerly on the staff of the Children's Hospital; aged 66; died, October 11.

William Amos Mansfield, Barberton, Ohio; Cleveland University of Medicine and Surgery, 1895; health officer; on the staff of the Citizens Hospital; aged 71; was found dead, November 1, in his garage, of carbon monoxide poisoning.

George Dalton Grimes, Houston, Texas; Jefferson Medical College of Philadelphia, 1902; member of the State Medical Association of Texas; aged 52; died, July 29, in St. Joseph's Hospital, of streptococcic meningitis.

Charles Lee Blanks, Tulsa, Okla.; Beaumont Hospital Medical College, St. Louis, 1892; member of the Oklahoma State Medical Association; aged 62; died suddenly, August 4, near Elvins, Mo., of heart disease.

Samuel Henry Hairston ⊕ Meridian, Miss.; Louisville (Ky.) Medical College, 1904; member of the American College of Surgeons; aged 50; died, October 20, in the Meridian Sanitarium, of coronary thrombosis.

Robert Randolph Grant ⊕ Plaquemine, La.; Medical Department of the University of the City of New York, 1891; president of the Iberville Parish Medical Society; aged 64; died, October 9, of pneumonia.

Orlando B. Longenecker, Dayton, Ohio; Hospital College of Medicine, Louisville, 1884; aged 71; died, October 28, of glandular hyperplasia of the prostate gland, acute urinary retention and paralytic ileus.

John Frederick Escher, San Diego, Calif.; Kentucky School of Medicine, Louisville, 1878; aged 86; died, September 18, of chronic nephritis, arteriosclerosis, senile dementia and valvular heart disease.

James A. Summerlin ⊕ Pelham, Ga.; Gate City Medical College, Texarkana, Texas, 1907; past president of the Colquitt County Medical Society; aged 52; died, October 7, of cerebral hemorrhage.

William Grant Casenburg, Knoxville, Tenn.; Tennessee Medical College, Knoxville, 1897; member of the Tennessee State Medical Association; aged 57; died suddenly, October 18, of heart disease.

Emmett James Howell, Eureka, Utah; Rush Medical College, Chicago, 1905; aged 55; died, June 6, in St. Mark's Hospital, Salt Lake City, of pulmonary tuberculosis and tuberculous spondylitis.

George G. Leist, Circleville, Ohio; Medical College of Ohio, Cincinnati, 1891; member of the Ohio State Medical Association; aged 74; died, September 10, of intestinal obstruction.

Abraham Bassman ⊕ St. Louis; National University of Arts and Sciences Medical Department, St. Louis, 1914; aged 50; died, September 16, in the Jewish Hospital, of bronchopneumonia.

Frank Albert Decker, Reardan, Wash.; College of Physicians and Surgeons, Keokuk, Iowa, 1919; served during the World War; aged 34; was killed, October 2, in an automobile accident.

Manuel Justo, Welch, W. Va.; Johns Hopkins University School of Medicine, Baltimore, 1923; aged 36; died, October 20, in St. Luke's Hospital, Bluefield, of carcinoma of the lung.

Charles Samuel Sakowitz, New Haven, Conn.; Yale University School of Medicine, New Haven, 1928; aged 25; died, October 7, in Saranac Lake, N. Y., of pulmonary tuberculosis.

Clara Eugenia Finney ⊕ Modesto, Calif.; Stanford University School of Medicine, San Francisco, 1920; aged 45; died, August 17, of skull fracture received in an automobile accident.

Jerome Augusta Boarman, Kansas City, Mo.; University Medical College of Kansas City, 1896; aged 69; died, September 12, in St. Joseph's Hospital, of carcinoma of the esophagus.

James Franklin Forehand, Bardwell, Texas; Memphis (Tenn.) Hospital Medical College, 1901; aged 75; died, September 23, of carcinoma of the left cheek and of pneumonia.

Robert Wilson Selby ⊕ Dover, Pa.; University of Michigan Medical School, Ann Arbor, 1913; aged 45; died, October 15, in the Johnston-Willis Hospital, Richmond, of septicemia.

John Frederick Miller, Andover, S. D.; University of Illinois College of Medicine, Chicago, 1905; aged 53; died, November 11, in the Peabody Hospital, Webster, of pneumonia.

Albert George Wright ⊕ Fenton, Mich.; Detroit College of Medicine, 1896; member of the school board; aged 65; died, October 14, in the Hurley Hospital, Flint, of pneumonia.

Elbridge Albert McIntyre, Chicago; University of Illinios College of Medicine, Chicago, 1927; aged 28; was found dead, November 7, in Mendota, Ill., of a gunshot wound.

Freeman A. Jones, Lansing, Mich.; Michigan College of Medicine, Detroit, 1881; member of the Michigan State Medical Society; aged 74; died, October 3, of diabetes mellitus.

John C. Thomasson, Georgetown, Ky.; Pulte Medical College, Cincinnati, 1889; for twelve years member of the school board; aged 73; died, October 4, of chronic nephritis.

William Alexander Hamilton, Paullina, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1900; aged 58; died, October 11, of heart disease.

Mattie Estella Cox, Rosemead, Calif.; Hahnemann Medical College and Hospital, Chicago, 1903; aged 68; died suddenly, recently, in Franklin, Ind., of heart disease.

Robert Smith Burket ⊕ Denver; University of Colorado School of Medicine, Denver, 1913; aged 41; died, recently, in St. Joseph's Hospital, of pulmonary tuberculosis.

Albert Griffith Eyestone ⊕ Gibsonburg, Ohio; Baltimore Medical College, 1900; served during the World War; aged 60; died suddenly, October 10, of heart disease.

William MacDonald Adams, Toronto, Ont., Canada; University of Western Ontario Medical School, London, 1912; aged 54; died recently, in St. Joseph's Hospital.

Robert B. Hiller, Thebes, Ill.; St. Louis College of Physicians and Surgeons, 1893; member of the Illinois State Medical Society; aged 69; died, October 4, of senility.

Eloy V. Pineda ⊕ Manila, P. I.; University of the Philippines College of Medicine, Manila, 1920; on the staff of the San Lazaro Hospital; aged 35; died, July 11.

William Henry Bates, Brooklyn; Medical Department of the University of the City of New York, 1863; aged 88; died, October 19, of carcinoma of the esophagus.

Guy Edward Krolick, Chicago; Chicago College of Medicine and Surgery, 1913; served during the World War; aged 41; died, November 9, of heart disease.

William Thomas Hamilton ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1887; aged 66; died, October 15, of myocarditis and chronic nephritis.

Henry Bergstein, San Francisco; Medical College of the Pacific, San Francisco, 1872; aged 83; died, August 10, of coronary sclerosis and chronic myocarditis.

John A. Lyng ⊕ Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1890; aged 64; died, September 27, of coronary sclerosis.

Edwin William Eberlein ⊕ St. Louis; Medical Department of Washington University, St. Louis, 1899; aged 54; died, November 1, of chronic myocarditis.

Charles Albert Cantrell ⊕ Plainview, Texas; Barnes Medical College, St. Louis, 1900; aged 57; died, August 6, in a local hospital, of cerebral hemorrhage.

James Byars, Austin, Texas; Medical College of Ohio, Cincinnati, 1882; Confederate veteran; aged 83; died, September 15, of a self inflicted bullet wound.

W. M. Curtis, Calhoun, Ga.; Atlanta Medical College, 1875; Confederate veteran; formerly a druggist; aged 84; died, September 30, of bronchopneumonia.

Adelheim Bernhard ⊕ Milwaukee; Kaiser-Wilhelms Universtität, Strassburg, Alsace-Lorraine, Germany, 1886; aged 69; died, October 17, of heart disease.

John B. McMackin, Iron City, Tenn.; Vanderbilt University School of Medicine, Nashville, 1890; aged 68; died, October 17, of cerebral hemorrhage.

Frederick Forbes Smith, Granville Ferry, N. S., Canada; Jefferson Medical College of Philadelphia, 1895; aged 63; died, July 17, of cerebral hemorrhage.

John Benton S. Egee, Philadelphia; Hahnemann Medical College of Philadelphia, 1875; aged 75; died, October 29, of portal cirrhosis of the liver.

Garrett Van Zandt, Chicago; Rush Medical College, Chicago, 1883; aged 73; died, October 24, of carcinoma of the lower lip and myocarditis.

Clara E. Jeter, Indianapolis; Beach Medical Institute, Indianapolis, 1886; aged 75; died, October 28, as the result of an injury received in a fall.

Jesse Cameron Pickett ⊕ San Francisco; Cooper Medical College, San Francisco, 1907; aged 51; died, October 6, in Ross, of rupture of the aorta.

Joseph Anthony Ebel ⊕ St. Louis; St. Louis University School of Medicine, 1920; aged 34; died, October 30, of chronic interstitial nephritis.

George Septimus Rennie, Hamilton, Ont., Canada; Trinity Medical College, Toronto, 1889; chief coroner; died, October 13, of pneumonia.

George Norman Powell, Letohatchee, Ala.; Medical College of Alabama, Mobile, 1896; aged 67; died, October 9, of arteriosclerosis.

John Nathaniel Fain, Greenville, Texas; Vanderbilt University School of Medicine, Nashville, 1891; aged 62; died, September 21.

Saunders James Thompson, Oklahoma City, Okla.; Meharry Medical College, Nashville, Tenn., 1916; aged 36; died, June 23.

Mack M. Colley, Memphis, Tenn.; Meharry Medical College, Nashville, Tenn., 1908; aged 54; died, July 13, of heat prostration.

Michael H. Houseworth, Mason, Ohio; Miami Medical College, Cincinnati, 1878; aged 73; died, October 23, of pneumonia.

John Dixon Webster, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1898; aged 73; died, August 11.

Lester E. Walker, Norwich, Conn.; New York Homeopathic Medical College, 1898; aged 57; died, June 14, of acute nephritis.

George W. Stewart, Muskogee, Okla.; Memphis (Tenn.) Hospital Medical College, 1890; aged 74; died, October 4, of hepatitis.

Albert Rogers, Seabeck, Wash.; Starling Medical College, Columbus, 1895; aged 63; died, August 4, of retroperitoneal sarcoma.

Webb J. Kelly, Piqua, Ohio; Bellevue Hospital Medical College, 1880; aged 73; died, September 21, of chronic nephritis.

Louis M. Coleman, Lake Charles, La. (licensed, Louisiana, 1896); aged 63; died, October 17, of nephritis.

C. T. Barker, Gate City, Va. (licensed, Virginia, by exemption); aged 77; died, October 6, of nephritis.

Bureau of Investigation

SOME MISCELLANEOUS "SPECIALISTS"

How Some Physicians Appraise the Intelligence of Other Physicians and the Public

The three schemes about to be described are being worked, at the present time, on the profession and the public, respectively. Each is operated by a physician:

Dr. F. J. James, Paris, Ill.—This man is circularizing physicians. He states in his circular-letter that he has been in the general practice of medicine for twenty years and has developed three *outstanding prescriptions, which he describes* as follows:

> "*No. 1.—Treatment for Renal Dropsy.* This prescription will cure 75 per cent of the cases, will remove the edema, and will restore the kidney to normal function *and in my experience has cured 98 per cent* of all cases coming to my attention, either acute or chronic. It is also very effective in Cardiac Dropsy.
>
> "*No. 2.—Acid Stomach and Fermentation.* This prescription will relieve the condition after the third dose. The coat will leave the tongue which the physic does not get rid of. This is not a soda preparation and one gallon can be made in your office at a cost not to exceed twenty cents. My experience has been that it will absolutely take care of 95 per cent of all stomach cases.
>
> "*No. 3.—An Absolute Specific for Acne.* You no doubt have had experience with this disease and have found how stubborn it is to handle. I absolutely guarantee this prescription to take care of it, 100 per cent."

Dr. James then states that it is not his desire to commercialize these prescriptions, but he feels that it is his duty to impart the information to his "brother physicians." Those who are interested in having them, should mail him a check for $3 and he will send the prescriptions, with instructions for their application. Dr. James adds, as an afterthought, that the prescription for "Acid Stomach and Fermentation" has in itself, for several years, paid all of his office expenses! Those who send the $3 get the following prescriptions:

"Spirit of Juniper	min.	45
"Vinegar Squill	min.	45
"Potassium Acetate	gr.	41
"Infusion Digitalis	min.	300
"Apocynum (Lloyds)	min.	16"

This is the combination that, according to Dr. James, has cured 98 per cent of all cases of renal dropsy, acute or chronic, that have come to his attention!

"Prescription No. 2" has at least the virtue of not being a polypharmacal monstrosity. It is nothing more marvelous than six ounces of pure hydrochloric acid in one gallon of distilled water, with some "red vegetable coloring to improve appearance." This is the prescription that has paid the doctor's office expenses for several years!

"Prescription No. 3," the "Absolute Specific for Acne," is:

"Acidi Salicylic	gr.	5
"Resorcin	gr.	10
"Phenol (90 per cent)	min.	20
"Sulphuris	dr.	1
"Zinci Oxidi	dr.	2
"Ungt. Aquae Rosae Qs	oz.	2
"M. Ft. Ungt."		

Dr. John W. Nelson, Jamestown, N. Y.—This man circularizes laymen in various parts of the country under the name, "*A. E. Daley," from Post-office Box 804,* Jamestown, N. Y. The "come-on" circular states that "A. E. Daley" is the fictitious name adopted by a physician in good standing in the American Medical Association and in the state, county, and local medical societies! He admits that the business is "possibly not strictly professional." The general tenor of the circular is to the effect that men who cannot perform sexually to the satisfaction of themselves and their wives should write to "Daley" for special information, which would then be sent. The recipient is told that after receiving this information, he is expected to send "Daley" $10.

Those who write to "Daley" receive another printed circular and a small rubber band, such as is purchasable in any stationery shop. The instructions are to put the band twice around the penis as high as possible, just before intercourse! The second circular also states that as soon as "A. E. Daley" receives the $10, he will reveal "some facts of great importance" that he has found from an "intensive study of the anatomy and function of our sexual organ." Those that send the $10 get a *mimeographed sheet* of four short paragraphs, conveying *no* information that is *not* the public property of every individual who has reached maturity.

Dr. B. J. Cline, Poplar Bluff, Mo.—*This is another* physician who has prescriptions to sell. His price, also, is $3, but he gives twice as many prescriptions for the money as does Dr. James. Dr. Cline's first prescription is described as one that "absolutely controls Whooping Cough almost 100 per cent and very cheap to make." He also throws in an "injection treatment" for the same disease. His second prescription is for acute or chronic poison ivy inflammation. This, he assures *us, cures in 99 per cent of the cases and only costs 25* cents a gallon to make! Prescription No. 3 is for sciatica and is also "good for any kind of neuralgia"; this, too, is inexpensive. The fourth prescription is an enema for the treatment of pneumonia; prescription No. 5 is for hay fever and while Dr. Cline does not claim that this permanently cures, he asserts that it will absolutely control the disease through its season, which most hay fever sufferers would doubtless consider as good as a cure. The sixth and last prescription is for venereal warts, and said to be a caustic salve that is "very easy to make and very cheap."

Dr. Cline, unlike Dr. James, makes no claims to originality in these prescriptions; he admits they are not original with him. He states that through a large company, he has access, indirectly, to every medical journal published in the world, "which costs me a nice sum, and I am giving you the best gleanings up to the minute." It appears, also, from the material that Dr. Cline sends out, that he has, in addition to these six prescriptions, a "patent medicine"—"B-J-C Capsules" of the Cline Medicine Company, Poplar Bluff, Mo. The capsules are said to contain sandalwood oil, copaiba, haarlem oil, and 2½ grains of salol.

Such incidents as these just detailed *do not redound* to the credit of the medical profession. It is especially disheartening, from the standpoint of scientific medicine, that there should be a sufficient number of physicians to make it a profitable thing for Drs. James and Cline to offer to sell prescriptions to men who are already graduates of medical schools and engaged in the practice of medicine.

As to the scheme exploited by Dr. John W. Nelson of Jamestown, N. Y., it is repugnant alike to the ideals of business and of medicine!

Correspondence

EDUCATION OF THE DIABETIC PATIENT

To the Editor:—Two thousand questionnaires were recently sent out for me at my request by the Chicago Dietetic Supply Company to its patrons. Five hundred similar ones were sent to names of diabetic patients of no known connections. Practically all were in communities smaller than a hundred thousand, and rural localities were given preference.

About 12 per cent of replies were received, but it should be realized that, as often happens, this is a selective and not a representative minority, they being mostly those proud of their diabetic doings that reply at all. Comparisons are admissible between members of the reporting group, but inferences may not be drawn as to the diabetic population at large.

For instance, 70 per cent of those replying use insulin, although it is most unlikely that even 15 per cent of the assumed million in the United States are using insulin. But it is significant as to what the lone practitioner is doing, single handed, that, of these 70 per cent using insulin, 76 per cent learned at home, never having been at a clinic, yet with exactly one patient reporting results less than "good."

It should be noted that 85 per cent of these insulin patients have been on a quantitative diet, which figures certainly do not apply to insulin users in general, but which do somewhat explain *the uniformly good results in* this group.

Clinic-training shows its value, 83 per cent of clinic-trained patients remaining sugar-free, as against 58 per cent of home-trained.

Of those replying to why more patients are not receiving modern treatment, 70 per cent blame "ignorance," not specifying whose; 60 per cent—unflattering as it may be—blame the incompetence or, more often, the indifference of available physicians, many naming all three factors. Forty-five per cent arraign the expense, especially the cost of insulin. Thirty per cent fear that insulin is habit-forming; 23 per cent fear reactions, though only 11 per cent fear the needle. Eighteen per cent have tried advertised "cures," mostly with zero results, though a few fondly think they "help some."

The value of diabetic manuals is strikingly shown; 70 per cent of book-owners are keeping sugar-free, as against 38 per cent of the bookless; and yet, 41 per cent of these people have never been advised to get a book and 16 per cent have not even seen one. Owners of the divers manuals represented are almost unanimous in the verdict that the books help.

A feeling exists among practitioners, abetted by a few specialists, that diabetic treatment is a specialty, not lightly to be trifled with by the humble family doctor, as he is liable to do more harm than good. To get current opinion, sixty questionnaires were sent out to eminent internists. Fifty-four replies were received, and 90 per cent agree. They concur that it is practicable for even the small-town doctor to treat diabetes, but not without the home-testing of urine, or without the patient having a book. They regard routine use of insulin without a quantitative diet or without keeping sugar-free as liable to prove eventually disastrous.

Many of these internists also filled in patient's questionnaires in a manner representative of the typical diabetic patient in their communities. Unanimity here is also of unusual degree. They state that in 1930 the average diabetic patient is not under treatment but has dabbled with "cures"; his urine is not home-tested but always shows sugar. Though not afraid of the needle, he has never used insulin, for he feels that when he once starts that, he is about done for! He has never been on a weighed or measured diet, nor has he ever seen or been advised to get any of the diabetic manuals. He would like elementary diabetic instruction classes held near him.

DON H. DUFFIE, M.D., Central Lake, Mich.

PRIORITY IN TREATMENT OF BROMIDE INTOXICATION

To the Editor:—In THE JOURNAL, October 25, Weidman under this title gives credit to Wile and his co-workers for being the pioneers in the application of the biologic fact that the administration of chlorides hastens the elimination of bromides.

Permit me to draw your attention to the fact that prior to or at least simultaneously with Wile, I recommended the salt treatment for bromism. At the annual meeting of the American Dermatological Association in Washington in 1922 I stated (*Arch. Dermat. & Syph.* **6**:559 [Nov.] 1922) in a discussion of a paper on drug eruptions: "The facts mentioned by Dr. Wile, that chlorides replace the bromides in the body, has induced me for many years to give patients with bromide eruption either a diet rich in salt or to administer calcium chloride by mouth." Dr. Wile in closing the discussion on his paper on bromide exanthems answered (p. 563): "Dr. Goldenberg's discussion brings out a therapeutic suggestion of great value which we have had occasion to employ, and which is very instructive. He said he had been accustomed to give patients with a bromide rash sodium chloride. . . ."

Whoever was the originator of this mode of treatment, I do not know. I do not claim any originality or priority. I have adopted it from the late Dr. Julius Rudisch, with whom I frequently discussed the topic during our rounds at Mount Sinai Hospital, and I believe it is not more than fair that our names should be included in mentioning the authors of the salt treatment in bromism.

HERMANN GOLDENBERG, M.D., New York.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

SCARLET FEVER IN THE NEGRO

To the Editor:—I have a patient, a Negro boy, aged 14, with a temperature of 100, sore throat, headache and itching skin. I suspect scarlet fever since there is some around here. How does one tell when a Negro has scarlet fever when the skin is so dark the scarlet rash cannot be seen?

R. E. GRAY, M.D., Eldora, Iowa.

ANSWER.—As a rule, it is not true that scarlet fever rashes cannot be seen in Negro patients. On the contrary, the rash can usually be seen without difficulty. Its color will vary from the usual one of scarlet fever in light patients to an increasingly bluish tint in the darker skins. In quite dark skins the compression of the skin with a glass slide is an aid in dispelling the hyperemia and in bringing out the contrast of rash with normal skin color.

In addition to the rash the usual symptoms of diagnostic value in others apply equally well to the Negro.

Sore throat, accompanied by nausea and vomiting, is always suggestive of scarlet fever.

When there is a question of scarlet fever in either Negro or white patients a culture on blood agar plates which is negative for hemolytic streptococci is of value in excluding scarlet fever, and if the absence of hemolytic streptococci is persistent one may be sure that the disease is not scarlet fever.

Of course, if the atrium is a wound as in surgical scarlet fever or the uterus as in puerperal scarlet fever the cultures must be taken from the wound or uterus as well as from the throat. As a rule there is little more difficulty in the diagnosis of scarlet fever in Negroes than in white people and the same diagnostic points apply.

POSTPUERPERAL ENDOCARDITIS — DISULPHAMIN

To the Editor:—I will appreciate any help on the following: 1. A patient, aged 25, was delivered prematurely by midforceps. At 11, she had a severe rheumatic fever leaving her with a mitral stenosis and aortic regurgitation. One vaginal examination under aseptic technic was done in her home. Feces were encountered during the delivery. An unexplained pytexia, not typical of a puerperal septicemia, was finally found to be caused by a positive blood culture, which showed anhemolytic streptococcus, *Staphylococcus aureus* and colon bacillus. It is now almost eight weeks since the delivery and the patient still has a similar chart and seems to be failing gradually. Do you believe this to be a flare-up of her old illness or possibly infection introduced at time of delivery? What would be your course of treatment in view of cardiac complications? 2. Have you any data on the value of disulphamin (American Bio-Chemical Laboratory) as a streptococcocide? Would you classify this case as one of puerperal septicemia or a bacterial endocarditis? Please omit name.

M.D., Massachusetts.

ANSWER.—1. Regardless of whether or not bacterial endocarditis is present now, this condition at first was most likely an exogenous puerperal infection. It is difficult to prove that the entire picture is due to a flare-up of old valvular lesions. The colon bacillus and *Staphylococcus aureus* are nearly always introduced from the outside at the time of delivery. The cardiac complication does not call for a radical change in the usual treatment for puerperal sepsis. Thus far, no specific drugs have been found for this condition, so measures must be used to build up the patient's resistance. These include forcing nourishing food, ample fluids by mouth, rectum and subcutaneously, fresh air, sunlight, sedatives for pain, hypnotics to secure sufficient sleep and rest, tonics, isolation, care of the bowels and bladder, and also proper moral support. Small and repeated blood transfusions are frequently helpful and, in the case cited, digitalis is surely indicated. Antistreptococcus serums and vaccines are usually without value and are sometimes harmful. Occasionally they have apparently produced a cure. Nursing should, of course, not be permitted. From time to time an examination should be made to rule out some surgical complication, such as an abscess, which may arise. The case cited should be classified as one of puerperal septicemia.

2. According to an advertising circular received in March, 1929, Disulphamin is chemically "Amino-Orto-Benzoil-di-Sulfo-Nucleo-Formin-Sodium Bicamforated." According to a circular received in August, 1929, it is chemically "orto-oxibenzoyl-sulphon-nucleino-formol-sodium-tetradimethylamino-antipyrin-bicamphorated." These designations are meaningless to chemists. They resemble other instances of pseudoscientific terminology wherein names of a chemical group, appearing as part of the name of this or that ingredient, are strung along to form an impressive sounding designation. While such imposingly named products have impressed many a medical man, they have usually turned out to be just a mixture of previously known substances. Good evidence should be supplied to show that one or the other designation applies to the product marketed as Disulphamin before this product is given serious consideration by physicians.

The American Bio-Chemical Laboratories, Inc., have not requested an examination of Disulphamin by the Council on Pharmacy and Chemistry nor has the Council given consideration to such a product. The American Bio-Chemical Laboratories have been sending advertising for "Disulphamin" to state medical journals with an inquiry regarding the cost of advertising and this letter is signed by Dr. L. Tomarkin. For some time the Tomarkin Foundation, Inc. (which had Carlos Tomarkin as president), has been exploiting a tuberculosis treatment called Catalysan Tomarkin, stated to have been developed by one Dr. Leandro W. Tomarkin.

GLANDULAR THERAPY OF OBESITY WITH IMPOTENCE

To the Editor:—Please advise me as to the care of this patient: A man, aged 38, weighing 278¾ pounds (126 Kg.), 5 feet 10 inches (178 cm.) tall, came to me, February 25. He was of a definite type of thyroid obesity. He had coarse hair and rough horny skin and was dull and sullen. The pulse was slow (50-60). He had been obese since childhood. His basal metabolism was minus 30. I gave him hygienic instructions, including a reduction diet and exercises. In addition, his medication has been desiccated thyroid (five times the strength of fresh gland) in huge doses, varying from 3 to 15 grains (0.2 to 1 Gm.) daily, depending on his reflexes, nervous irritability, tremor, heart rate and the rapidity of his loss in weight. June 22, he weighed 215 pounds (97 Kg.). I have now found the amount of thyroid which he apparently needs (i. e., from 5 to 6 grains, or 0.3 to 0.4 Gm., daily); by that I mean he does not develop signs of toxicity on this dosage, and if he gets less than this quantity he begins to gain weight rapidly. On this dosage his basal metabolism varies from minus 10 to plus 5. Since June 22, however, which is three months ago, he has held this weight varying from 210 to 220 pounds (95 to 100 Kg.). His skin is fine, the coarse horny texture has entirely disappeared, and his hair is smooth and oily (not so dry and coarse). He is more potent sexually (his wife has commented on this). Mentally, he is dissatisfied with an occupation which he has followed for eighteen years and is preparing himself for a better position. He is not dull and sullen but mentally alert. His obesity is not generalized now. Briefly, the man has lost 60 pounds (27 Kg.) during the first four months of treatment and apparently will not lose further on this type of treatment; without it, however, he begins to gain quickly. As his obesity is not generalized now, it is more of the pituitary type (i. e., his arms, legs and lower thighs, neck and face have little excess fat), but from the breasts to the middle of his thighs he is obese. According to his height, 5 feet 10 inches, I believe he would be better off weighing from 175 to 180 pounds (79 to 82 kg.). In my opinion, this man's thyroid does not secrete sufficiently and he needs medication to correct that. In addition, some other endocrine gland is not acting in harmony (probably the pituitary). If I have given you sufficient data to advise me intelligently, there are several questions I should like to ask. 1. Is it probable that this man will have to continue taking thyroid permanently? 2. Is pituitary therapy satisfactory in this type of case? Should whole gland be given or just anterior lobe? What company's products can you recommend? How is it best administered? What are the signs of overdosage in an adult? Are there any signs of overdosage or toxicity (similar or comparable) to what is found when too much thyroid is given? What dosage is safe to begin with? I am writing to you because of the unconvincing report by the man to whom I referred the patient. I have sent several patients to him since my graduation—he is a former teacher of mine and has the reputation of being an excellent endocrinologist, but the patients resent his high fees and he does not send me sufficiently illuminating reports. Kindly omit name and city, if this is published.

M.D., California.

Answer.—1. While it is possible that this patient ultimately may be able to leave off taking thyroid, the probability, as deduced from the careful statement of the letter, is that he will have to continue taking thyroid permanently.

2. It is quite unlikely that any type of pituitary therapy will be of value in this case. Although there are some reports in the literature, there are few carefully authenticated cases in adults who have shown any relief from pituitary. If it is to be used at all, it would seem that the best preparation is the whole pituitary extract and the dose a rather large one, 0.3 Gm. (5 grains) three times a day. Probably the only benefit from this large dose will be to the manufacturer. The probabilities are that the only way this patient will lose any more weight is by the continuation of the thyroid in association with a low caloric diet.

DERMATITIS FROM CYANIDES

To the Editor:—Would you kindly supply me with the information, if any, as regards any ill effects of a patient working in the cyanide heat treating room of an industrial plant. Is there any characteristic dermatitis resulting from whatever fumes might come from cyanide vats?

F. E. Kirshman, M.D., Muncie, Ind.

Answer.—In case hardening and tempering, metals may be treated with cyanide baths. Usually potassium cyanide is utilized. Under the influence of heat, hydrocyanic acid fumes may be produced, particularly if the carbon dioxide content of the air is high.

In industrial heat treating rooms in which cyanide is used, both systemic poisoning and (or) dermatoses may take place.

The International Labor Office's "Occupation and Health" bulletin number 181, entitled "Cyanogen and Its Compounds," furnishes excellent descriptive material on all aspects of cyanide poisoning.

An article by Dr. Huntington Williams on cyanide poisoning (The Journal, March 1, p. 627) contains excellent descriptive material also of acute and nonfatal forms of cyanide poisoning.

Prosser White's "The Dermatergoses or Occupational Affections of the Skin" describes the characteristics of cyanide skin abnormalities.

The International Labor Office publication says, with reference to cyanide dermatitis: "Varieties of dermatitis due to cyanides are also important. In a fatal case reported by Bridge in 1923, the skin of the right arm of the victim had been removed in patches, as if it had been burned. Brownish-red coloration of the skin of the hands and forearm have also been reported; the nails in one case were almost black (Collins and Martland). In most cases only eczema or acne rosacea lesions are noted, and they are situated chiefly on the dorsal surface of the fingers and hands, on the wrist and at the elbow, and, more rarely, on the face, ears, and front or back of the neck. In its primary form the lesions occur in the form of extremely irritating papules or vesicles; scratching and consequent infection leads to secondary forms. The lesions are persistent and relapses are frequent; this dermatitis is aggravated by small wounds or by maceration of the skin, or by the removal of fat due to the use of certain solvents, as in electroplating."

PHENOBARBITAL (LUMINAL) AT PARTURITION

To the Editor:—A patient, aged 35, having one living child by a previous cesarean section, performed because of a pelvic contracture, was recently prepared for a second cesarean section three days before the estimated date of term. She was nervous and apprehensive and consequently was given 6 grains (0.4 Gm.) of phenobarbital two hours before time for the operation. No morphine or other opiates were given the patient. The usual fundal cesarean section was performed rapidly and no difficulties were encountered. The baby, when delivered, was livid and, though weakly, cried immediately. It failed to cry lustily from the start and breathed with difficulty but did not appear to have any obstruction. The child became cyanotic at intervals, and considerable frothy fluid exuded from the mouth. It was placed in an incubator and given oxygen as necessary. The child died about nine hours after delivery. It was believed to have been practically full term, as it was fairly free from vernix and the hair and nails were well developed. I could advance no logical reason why this baby should have died after receiving all forms of resuscitation and stimulation unless it could have been that the phenobarbital was responsible. Do you believe it probable or possible that the phenobarbital given the mother could have been in any way a factor in the production of death in this case?

George H Adler, M.D., Klamath Falls, Ore.

Answer.—It is hardly likely that the phenobarbital given to the patient shortly before the delivery of the baby was responsible for the death of the child. Larger doses than 6 grains (0.4 Gm.) have been given to patients in labor without any harm to their new-born children. It is unfortunate that a necropsy was not performed in this case. There are a number of reasons to explain the death of babies born even by cesarean section in which the amount of trauma is almost a minimum. A postmortem examination might have revealed a congenital anomaly that was incompatable with life. The child might have aspirated liquor amnii before it was removed from the uterus or it might have had asphyxia from some other cause. If the necropsy had failed to reveal any cause of death, then phenobarbital might be held responsible on the assumption that the child had an idiosyncrasy toward this drug.

TREATMENT OF COLITIS—USE OF RHUS ANTIGEN

To the Editor:—1. I have a patient with thyrotoxicosis and associated *emaciation, myocarditis and colitis, whom it is planned to improve with* rest and symptomatic treatment for eventual thyroidectomy. The only medication being used at present is small frequent doses of "bismuth" and 5 grain (0.3 Gm.) doses of barbital at bedtime. The patient has normal bowel movements for several days or a week or more which are interrupted by a paroxysm of diarrhea lasting from several hours to two days. Tincture of opium has been used to stop the diarrhea, with good success. Each attack of diarrhea is accompanied by the loss of the amount of body weight gained since the last previous attack. Would you recom*mend novatropine for the colitis? Kindly advise as to dosage and pre*cautions if you think this drug could be properly used. 2. What is the present status of the treatment of ivy poisoning with Rhus-antigen.

C. M. Bahnson, M.D., Jersey City, N. J.

Answer.—1. A roentgen examination of the colon would be an advantage in determining whether or not the diarrhea is due to retention of material in the proximal colon. If it is, then mild laxative treatment consisting of magnesia magma or castor oil, taken regularly as long as the patient is at rest, would be more likely to succeed than the constipating therapy that is being employed at present. The preoperative use of iodine is advisable in this case, because it would temporarily lessen the hyperthyroid tendency, which, no doubt, exaggerates the colonic reactivity. Novatropine is an artificial tropeine, from which no more could be expected than from atropine. It would merely act as an antispasmodic.

2. Rhus preparations have not proved effective as a means of immunization against ivy poisoning.

ALUMINUM IN BODY NOT CUMULATIVE

To the Editor:—I noticed in *McCall's* for march, I believe, an article about aluminum not being absorbed by the body. In the article quoted in The Journal (March 31, 1928, p. 1010) it says that "the metals *combine with both the white and the red cells of the blood to some* extent." Will not one metal, such as aluminum, be absorbed just as quickly as any other metal, such as iron or tin, by the body so that, if one metal could poison a person, another could?

J. A. Holton, Woodburn, Ore.

Answer.—The various metals behave quite differently in the body. Aluminum is but slowly absorbed. It is rapidly eliminated from the blood, chiefly by the bowels. The bile has been found especially rich in aluminum. It is eliminated to a lesser extent by the kidney. There seems to be no tendency for it to collect in the body; and, in spite of the fact that aluminum may frequently enter the body in small amounts in various ways, cases of chronic poisoning *from it have not been reported.*

SCANTY MENSTRUATION

To the Editor:—A multipara, aged about 35, who is inclined to be stout and phlegmatic, is regular with the menses, but there seems to be no color in the flow (about straw color). I cannot find a pathologic change to account for this, only stoutness. What can be the cause?

G. Glenn White, M.D., San Diego, Calif.

Answer.—Regular menstruation with scanty or watery flow is most often ascribable to debilitated general health; too frequent pregnancies may be a factor. Another relatively common cause of decreased or "thin" menses is derangement of the glands of internal secretion, notably deficiency of the thyroid gland. Determination of the basal metabolic rate should reveal the presence or absence of thyroid disturbance; if normal, special attention should be given to the maintenance of a well balanced diet, life outdoors, and avoidance of pregnancy until the return of robust health.

DANGERS IN USE OF X-RAYS

To the Editor:—We recently installed an x-ray apparatus with a separate fluoroscope and table. We do perhaps eight or ten fluoroscopic examinations a day and take a few pictures. We are not in the habit of using protective aprons or gloves and about the only bad results we have noticed to ourselves is an occasional mild dermatitis of the backs of our hands and a brittle condition of the nails, causing them to split and crack easily. What is the probable outcome to our general physical con*dition (blood picture), if any, if we continue as we are doing?*

M.D., Michigan.

Answer.—Fundamentally, x-rays are dangerous and due caution must be exercised in their use. A fair test would be to darken completely the room in which the apparatus is used and to use the fluorescent screen in the different locations occupied by those in the immediate vicinity and usual positions of the operators. If the screen fluoresces in the slightest degree, it should be considered dangerous and the protection is not ample.

It is evident that the inquirer is exposed to the action of the x-rays because of the dermatitis on the back of the hands and the brittle condition of the nails. He should be more cautious, because it is by repeated exposures that serious consequences will occur. There are many possibilities of which little is known, especially those concerned with the endocrines. As to the blood degeneration, one should bear in mind a leukopenia and the development of an aplastic anemia.

BLOOD IN FECES

To the Editor:—At a staff meeting of a hospital a case of carcinoma of the rectum, complicated by a rectal fistula from which came blood that was almost black, was reported and discussed. Nothing was said as to whether or not there was a hemorrhage from the anus. In intestinal hemorrhage it is accepted, I believe, that the color of the blood is diagnostically indicative as to the location of the lesion—the darker the blood, the higher up in the gastro-intestinal tract is the lesion. If a case of carcinoma of the rectum is complicated by a rectal fistula and if from *this rectal fistula comes blood that is dark, almost black, is the color of* the blood due to the fact that it came from and possibly had remained a shorter or longer time in the fistula, or might it be indicative of a lesion higher up in the digestive tract in addition to the rectal carcinoma, and might the color of the blood be solely due to the digestive process while on its way to the exit? Kindly omit name and address.

M.D., Washington.

Answer.—The appearance of dark tarry blood in the feces *is usually indicative of bleeding high up in the gastro-intestinal* tract. However, altered blood is frequently found in individuals with obstructive and ulcerating lesions of the colon and this is due to the formation of iron sulphide from the action of the *sulphide gases and the blood. The case here presented appears* to be one of this nature in that the blood has remained in the colon for some period probably because of the partial obstruction from the rectal carcinoma and the irritation of the fistula.

CAUTERIZATION OF THE CERVIX IN CHILD WITH ENDOCERVICITIS

To the Editor:—Would you advise cauterization of the cervix in a child, aged 10 years, who has had a gonorrheal endocervicitis for fourteen months? I have used the usual remedies and mixed vaccine, but the discharge and tenderness of the uterus continues. I should be glad to have suggestions regarding the treatment of such a case.

C. W. Harper, M.D., Chipley, Fla.

Answer.—There is as much indication to treat a 10 year old child who has gonorrheal endocervicitis with the electric *cautery as there is to treat an older individual.* The cautery should be used in this case because the other remedies have failed and also because cautery treatments usually produce a rapid amelioration of symptoms. After each cautery treatment *it may be helpful to apply a 10 per cent solution of mercuro*chrome-220 soluble not only to the cervix but also all over the vaginal mucosa. Prolonged hot sitz baths may likewise prove beneficial. The child should be isolated as much as pos*sible from other children, especially from younger girls,* who are very susceptible to gonorrheal vaginitis.

POSSIBILITY OF POISONING FROM MERCUROCHROME ENEMAS

To the Editor:—I would like to inquire if there is any danger of mercury poisoning resulting from enemas in which 15 grains (1 Gm.) of mercurochrome is added to one pint (475 cc.) of fluid.

M.D., Minnesota.

Answer.—There is not much danger, even though the contemplated dose is perhaps three times as great as the dosage used intravenously and 50 per cent greater than the oral dose. If the enemas were used daily for quite a long time, there might be sufficient absorption of mercurochrome to produce mercurialism, which would probably be first evidenced by stomatitis, the appearance of which should be an indication for discontinuing this therapy.

COMPLICATIONS OF PERNICIOUS ANEMIA

To the Editor:—Kindly advise me in the following case: A man, aged 60, has had pernicious anemia for several years. He has done well on liver and liver extract except that he complains a great deal of tingling, numbness and weakness in his limbs, which I attribute to sensory disturbance from the anemia. Please suggest a treatment for this phase of the case.

J. G. Busby, M.D., Salisbury, N. C.

Answer.—The numbness and tingling described may disappear with the improvement consequent on liver therapy, but this is not always the case. There is no specific therapy for the sensory disturbances.

Book Notices

A HISTORY OF THE CALIFORNIA ACADEMY OF MEDICINE, 1870 TO 1930. By J Marion Read. Boards. Price, $10. Pp. 186, with illustrations. San Francisco: California Academy of Medicine, 1930.

For the first twenty-one years of its existence, the California Academy of Medicine bore the title of the San Francisco Medical Benevolent Society. It was one of eighty societies, in a city numbering 150,000 people, classed as "benevolent" twenty-two years after the discovery of gold in Yerba Buena.

The biographic sketches include the presidents of the academy, beginning with Robert McMillan, a "forty-niner" who was content to practice medicine and resist the temptation of most of his fellows to go prospecting in the hills. The society seems to have been the center of some controversies, such as that over the first cesarean section performed in the state, the James King of William affair, and the seeming aspersion cast by Beverly Cole on the women of California, all of which were characterized by intense animosity, alining every physician on one side or the other.

The early practitioners of San Francisco were lured by a strong love of adventure which impelled so many to follow the trail of the "forty-niners." Dr. Samuel R. Gerry, one of three members of the first executive committee, migrated from Massachusetts to Chile and then to San Francisco, where he attended the first patient with cholera in the epidemic of 1849 and was made quarantine and health officer of the port of San Francisco. Another executive committeeman was Arthur Peronneau Hayne, who traveled from South Carolina to Paris and then to San Francisco; Robert McIntosh and Robert Kennedy Nuttall were young medicos who met in the antipodes and then started to practice in a tent in San Francisco, and assisted in the formation of the first medical society in San Francisco in 1850. To Victor Jean Fourgeaud, a member of the executive committee in 1873, belongs the honor of being one of the first of that illimitable band of California boosters. Educated in science, he used his trained powers of observation with the result that his essay "The Prospects of California" marked him as a pioneer in truthful advertising. In 1848 General Sutter sent to Fourgeaud a small ore specimen, which he tested and pronounced "pure gold," thus making the first test of metal in California. The third president of the benevolent society, Washington Ayer, was an eye witness of the first surgical operation performed under ether anesthesia at the Massachusetts General Hospital in 1846. At the fifteenth anniversary of the introduction of ether in surgery, he recounted the details of that momentous event, which was considered by Packard in his "History of Medicine of the United States" the best written account extant.

One feature of interest in the early society was the extreme heterogeneity of its membership. Mexican, Russian, Canadian, German, Irish, French and Scotch medical schools as well as a dozen in this country were represented. Native sons recently graduated from local schools joined the "forty-niners" from the four corners of the earth, but they had one thing in common—they were trained graduate physicians. When the question of licensing became acute, the San Francisco Medical Benevolent Society regarded itself as a state medical organization and proceeded to appoint the board of medical examiners for the state. In 1889, the membership of sixty-six physicians decided that, on account of the incongruity existing between the name and its function, the San Francisco Medical Benevolent Society should change its name to the California Academy of Medicine.

The academy period, 1891-1913, was marked by the building of a home which established an indebtedness of $12,500. The president in 1899 was the brilliant John F. Morse, whose fame rested on the first successful wiring of an abdominal aneurysm. Programs of this period featured such persons as R. Beverley Cole, President of the American Medical Association; William Watt Kerr, the beloved teacher, and Douglass W. Montgomery, who was president of the academy during the trying period of the financial collapse in 1898, when the society lost its home.

Programs for the years 1896 and 1897 marked the inauguration of the habit that was the forerunner of the present and only form of meeting in which addresses are given by imported speakers; they drew on medical officers in the army, navy, public health and other federal services, and among other speakers of this era was Dr. M. J. Rosenau, who talked on "The Practical Value of Bacteriology in Quarantine Work." The history recounts the true situation with regard to the plague epidemic of 1900, concerning which the newspapers connived to keep facts under cover, prompted by short-sighted commercialism.

There was a temporary abrupt termination of the society's activities in 1906 by the earthquake and fire, which put the organization in a somewhat moribund state, lasting until the modern period of reorganization.

Under the presidency of Dr. T. C. McCleave, dinner meetings were held and the assumption of social aspects in connection with the scientific program proved popular. The secretary-treasurer's records prior to 1916 are apparently nonexistent, but in that year LeRoy Briggs installed the present system of accurately recording the minutes. The academy's activities suffered curtailment in war time, which was felt by every nonmilitary organization. Dr. Ray Lyman Wilbur, president for 1917, spent much time in the national capital in war work, and many others were in the war service. One of the versatile men of this time, Saxton Temple Pope, was the secretary of the academy, a great surgeon whose interest in other fields prompted him to make a study of bows and arrows after meeting Ishi, the sole survivor of the Yana tribe of Indians. Pope made seventeen expeditions hunting with a bow and arrow, the last one in Africa. The volume gives a fairly complete outline of the activities of each year from 1915 to 1929. The careers of many prominent academy members are outlined in detail. Dr. A. W. Hewlett, president in 1922, became professor of medicine in Stanford University Medical School, which chair President Ray Lyman Wilbur had vacated to become president of the university. Hewlett served for six years as a member of the Council on Pharmacy and Chemistry of the American Medical Association, during which time the report of his work on "The Clinical Effects of Natural and Synthetic Sodium Salicylate" was published. A series of tables giving the program of meetings from 1915 to date are included in this history together with an analysis of attendance at meetings from 1927 to 1930 with the locations of guests and members. Appendixes include a list of officers from 1870 to 1930; membership roll as of Jan. 1, 1930, arranged by counties, and a copy of the constitution and by-laws. Numerous pictures of prominent members are included in the book. The reader is referred to a list of printed sources used by the compiler of this volume. The California Academy has made it known to the members of the profession that its chief function is to bring distinguished scientists who are making current medical history to San Francisco that its members might learn of medical advancement, yet no press notices reach laymen. California physicians will read this delightful volume with complacence, tracing the growth of a substantial and helpful organization through the vicissitudes of its formative period. Physicians of other states will find in this history corollaries of the problems of any medical group.

Die Verästelung der Arteria renalis in der Niere des Menschen: Eine historisch-anatomische Untersuchung. Von H. M. Hou-Jensen, Prosector anatomie. Paper. Pp. 140, with 59 illustrations. Berlin: Julius Springer, 1929.

The author precedes the report of his own observations with an extensive representation of the various theories regarding the structure of the kidneys, held since Galen. From the detailed description of his own investigations only a few statements can be pointed out. The length of the renal artery, which originates as a single trunk (78 per cent), is on the right side 5.2 cm., on the left 5.3 cm. It usually ramifies near the hilus, by dividing into three or four branches. Aberrant arteries can be found in one out of five kidneys. The author differentiates between a dorsal arterial trunk, which enters unramified into the hilus, and a ventral trunk, which is divided fanlike. The blood supply of each lobe is provided by at least two arteriae interlobares. One part of their branches leads exclusively to the columnae bertini (insignificant); the other branches form the arteriae arciformes above the bases of the pyramids, and branches are also sent to the columnae and to the connective tissue sheaths of the larger vessels. The cortex arteries originate mostly in trunks that come either acute-angled or right-angled out of the arteriae arciformes or out of their terminating ramifications. They always merge into the arteriae afferentes and send out only detached rami capsulares, rarely also directing thin branches to the round meshy net of capillaries. The off-branching of vessels from the vasa afferentia to the capillary net was noted in only 2 per cent of the cases. The blood supply of the medullary substance is mainly postglomerular. Direct branches from the vasa afferentia, respectively branches of the arteriae arciformes (arteriae rectae verae), the existence of which was already doubted by Lee-Brown, are rare and of no significance for the normal circulation. Arteriovenous anastomoses could not be demonstrated by the author.

Outline in Obstetrics for Nurses. By F. W. Rice, M.D., Instructor in Obstetrics, Iowa Methodist Hospital, and Broadlawns General Hospital, Des Moines, Iowa. Cloth. Price, $2. Pp. 228, with 56 illustrations. St. Louis: C. V. Mosby Company, 1930.

Just why this book was published is difficult to tell. The author says, "This outline is not intended as a textbook. It saves the time of the teacher in that he can lecture faster and need not stop to spell words. It enables the student to pay more strict attention to the lecture and not lose half of it while she writes down the other half." There are excellent books on obstetrics for nurses, especially those by De Lee and Van Blarcom. If a nurse possesses either of these two books she has no need for the present outline and if she owns only the latter she will not learn enough about obstetrics from it. The illustrations in this book consist of photographs reproduced from seven different books on obstetrics and a few crude drawings. The latter could advantageously have been replaced by more illustrations from the seven textbooks. Fifty pages are entirely blank for the use of notes. A large proportion of the space on the remaining pages is likewise empty, so that the actual printed material could have been published in a small booklet. The best part of the book is the introduction, which contains sound advice to prospective nurses.

Les vomissements chez le nourrisson: Sténoses pyloriques et duodénales. Par E. Lesné, et Maurice Coffin, médecin de l'Hôpital Bon-Secours. Paper. Price, 25 francs. Pp. 139. Paris: Gauthier-Villars & Cie, 1930.

The authors have presented in this brief monograph a clinical bedside description of the most common types of vomiting in the infant, including a discussion of the etiology, pathogenesis and treatment. They observe that vomiting may be either a casual episode or a persistent phenomenon demanding attention. The authors find that in the normal infant the stomach is empty three hours after feeding. Also the motor activity of the stomach varies with the type of milk ingested. Cow's milk passes through more rapidly than human milk. Radioscopic examination of the normal infant's stomach indicates an easy and rapid passage of the contents into the small intestine. The occasional episodic vomiting in an infant may be due to alimentary disturbances induced by underfeeding or overfeeding, irregular hours of feeding, vitamin deficiency, puerperal infection or breast abscess in the mother, dyspepsias, gastro-enteritis, or infectious diseases. Meningitis, encephalitis, whooping cough, tracheobronchial adenopathy, severe icterus and sepsis may also be associated with vomiting. The authors find that neuropathic children may be subject to vomiting particularly if brought up in an unsuitable environment under an emotional mother. The third chapter is devoted to grave paroxysmal types of vomiting found in such varied clinical conditions as intestinal invagination, strangulated hernia, alimentary anaphylaxis, cyclic vomiting and gastropylorospasm. Anaphylaxis to the milk is found to be the most frequent type of alimentary anaphylaxis in the infant. Next in frequency is anaphylaxis due to eggs. Small amounts of these foods in sensitized infants cause alarming symptoms and even collapse and death. The diagnosis and treatment of pylorospasm are discussed in detail. It is pointed out that in pylorospasm there is no stasis, in contrast with the condition in pyloric stenosis.

The last chapter is devoted to a discussion of pyloric and duodenal stenosis, or the types of vomiting associated with stasis. In determining the presence of gastric stasis, two methods are advocated by the authors, the passage of a stomach tube and the method of double weighing. In the latter method, measured amounts of milk are given and the infant is weighed immediately after the last attack of vomiting. It is frequently found that the vomitus weighed more than the last meal given, thus showing the existence of a retention. The presence of a milk residue in the stomach of an infant four hours after the last feeding is presumptive evidence of mechanical obstruction. The incidence and pathology of pyloric stenosis are discussed. Two clinical types are mentioned. There is an acute type in which spasm plays little part. Of less frequent occurrence is the chronic type, in which both stenosis and spasm are present. The authors think that the presence of spasm tends to mask the diagnosis in the latter form. They attach little or no diagnostic importance to the presence or absence of a palpable pyloric tumor. As for treatment, they are decidedly in favor of surgical methods and do not advise medical treatment of pyloric stenosis. The mortality statistics of various surgeons are presented in detail and the importance of expert postoperative care is stressed. Duodenal obstruction is considered to be an important condition to differentiate from pyloric stenosis. Etiologically it is thought to be due to a developmental atresia or fetal peritonitis. Radiographic examination is said to show a dilated duodenum, and the treatment is surgical.

This monograph considers in a broad way the various phases of vomiting as it occurs in infancy and presents a clinical review which will be useful to students and practitioners.

A FRONTIER DOCTOR. By Henry F. Hoyt. With an introduction by Frank B. Kellogg. Cloth. Price, $3.50. Pp. 260, with illustrations. Boston: Houghton Mifflin Company, 1929.

The current year has seen several contributions to autobiographic works by physicians. At the present moment the book by Axel Munthe is listed among the best sellers and is recognized as one of the most romantic works available for the public interested in medical practice. The work by Dr. Hoyt is a book of a different character. Munthe has confessed that much of his book represents the borderland between truth and fiction. Dr. Hoyt's work is solid fact about a romantic life. He practiced medicine in Texas, New Mexico and the Far West at a time when life was a struggle. In the Spanish-American War he served in the Philippines. He earned his education as a cowboy and as a doctor in frontier districts. He knew that famous outlaw called "Billy the Kid." His life is a most interesting story and will appeal to physicians who have served in a similar territory or under similar conditions.

A SYSTEM OF BACTERIOLOGY IN RELATION TO MEDICINE. Volume I. By F. W. Andrewes, J. A. Arkwright, and others. Medical Research Council. Cloth. Price, £1 1s. 0d. net. Pp. 374, with illustrations. London: His Majesty's Stationery Office, 1930.

The previous volumes of this system have been reviewed on various occasions in THE JOURNAL. They have concerned primarily the various classifications of bacterial organisms. The present volume has an introduction by Balfour and provides not only a good history of bacteriology but chapters of general subjects in this field, including morphology, physiology, growth and reproduction, disinfection, bacterial metabolism, classifications and variations. The work is exceptionally complete. Each of the chapters is supplemented by a good bibliography. The entire series of volumes constitutes as important a reference work as is available. The illustrations, particularly in the section on history of bacteriology, are well selected and handsomely reproduced, so that the system may, as a whole, be recommended without reservation to every student of the subject and to every physician with a special interest in this field.

HIERONYMI FRACASTORII DE CONTAGIONE ET CONTAGIOSIS MORBIS ET EORUM CURATIONE, LIBRI III. Translation and notes by Wilmer Cave Wright, Ph.D., Professor of Greek in Bryn Mawr College. Cloth. Price, $4.50. Pp. 356. New York: G. P. Putnam's Sons, 1930.

The year 1930 is the four hundredth anniversary of the publication of the famous poem by Fracastorius on the subject of syphilis; hence, it is especially interesting that Professor Wright should make available, as one of the volumes on the history of medicine issued under the auspices of the Library of the New York Academy of Medicine, a new translation of this work, supplemented by an excellent introduction in which are quoted some of the most important opinions of the work that have been published from time to time throughout the world. The volume is printed with the Latin on one page and the English translation on the opposite page, so that it thus becomes available as a reference for physicians who may be attempting to brush up on the classics.

SONDERBÄNDE ZUR STRAHLENTHERAPIE. Herausgegeben von Professor Dr. Hans Meyer. Band XV: Die Röntgenbehandlung der Nervenkrankheiten. Von Prof. Dr. Otto Marburg, Vorstand des Neurol. Institutes der Wiener Universität, und Doz. Dr. Max Sgalitzer, Leiter des Röntgenlaboratoriums der I. chir. Klinik der Wiener Universität. Paper. Price, 15 marks. Pp. 213, with 4 illustrations. Berlin: Urban & Schwarzenberg, 1930.

The authors give a complete survey of the therapeutic possibilities and results of roentgen therapy in disorders of the nervous system. The basis of their report is furnished by experiences gleaned in cooperation with the surgical clinic of von Eiselsberg in Vienna. At the same time they collected and abstracted the literature pertaining to this topic and critically sifted this material. The authors profess that their main object was to outline and determine the indications for the application of this method and also to present results as far as it is possible to do so, considering that a rational roentgen therapy of nervous disorders dates back only for about ten years. In order to facilitate for the neurologist an understanding of the possibilities of roentgen therapy, in three introductory chapters the authors discuss the fundamentals of the physics of x-rays, their biologic action and the practice of therapeutic irradiation. The therapeutic chapters are divided according to the pathologic conditions to be treated. A quick orientation is facilitated by a summary attached to each chapter that concisely reports all the leading points elaborated in the text. While the authors are convinced that further observation and technical progress will furnish results above the present accomplishments, their reports reflect a sober and sound scrutinizing of results. This book may truthfully be considered a valuable guide for anybody interested in this rather new field of therapeutic endeavor.

THE MORPHINE HABIT AND ITS PAINLESS TREATMENT. By G. Laughton Scott, M.R.C.S., B.A. Cloth. Price, 5/- net. Pp. 94. London: H K. Lewis & Company, Ltd., 1930.

The "painless treatment" consists of a modification of the Lambert-Townes treatment plus the use of phenobarbital. In the first four chapters, on introduction, etiology, symptoms of morphinism and the avoidance of shock in treatment, nothing new is given. In the fifth chapter, on special medication, the author explains that his treatment consists of the Lambert mixture with the xanthoxylum replaced by water and that the drastic purgation is also eliminated. Both of the points were first advised in 1915 by the editor of THE JOURNAL (see article on drug addictions in the "Handbook of Therapy"). The treatment consists of the withdrawal of the morphine in from seven to twelve days under a gradually developed tolerance to the belladonna and scopolamine mixture, with free and increasing doses of phenobarbital. The mixture is started with 5 minims (0.3 cm.) hourly and the dosage is steadily increased until a tolerance is developed in which some patients exceed an hourly dose of 1 drachm (4 cc.) without developing delirium or toxic symptoms, just below the point of delirium, where the pupils are dilated but still reaction to light is best; at the same time the morphine is reduced and phenobarbital is used as necessary for sleep and to reduce nervous symptoms. Medication ceases at night and the bowels are kept well open; but no exhausting purgation is given. The author believes that the end-results are better because the patient is spared the shocks of delirium, of merciless diarrhea and of sleepless nights. He states that it is not possible for any physician who has not had some experience in treating these cases to make a satisfactory withdrawal, however well provided he may be with instructions of actual treatments. The remaining five chapters are on withdrawal in three cases, the diary of a patient, and a short description of twenty consecutive cases treated during the past five years. Eleven of the patients were physicians, one was a dentist, five were women and three were men. There is a short chapter on convalescence, the conclusion, and an appendix consisting of twenty-four pages written by a medical morphinist who after three treatments, a scopolamine "knock-out," a Jennings (whom he accuses of being an ex-morphinist) and a modified scopolamine treatment, all failures, finds Dr. Scott's method the only reliable one. All of the references are from American medical writers.

Principles of Bacteriology in Fifteen Lessons. By Arthur A. Eisenberg, A.B., M.D., Director of Laboratories, Sydenham Hospital, New York City, and Mabel F. Huntly, B.S., R.N., Director of the School for Preliminary Courses in Nursing, Philadelphia. Fifth edition. Cloth. Price, $2.75. Pp. 322, with 62 illustrations. St. Louis: C. V. Mosby Company, 1930.

This book is intended for use in training schools for nurses. As is true of almost all the textbooks intended for this purpose, too much material is presented. All that can be expected of the nurse is that she absorb certain fundamental principles; she has neither the time nor the inclination to interest herself in details. The present volume could be made more valuable by the elimination of such material. In general, the point of view is up to date and the facts given are as nearly correct as is possible to expect in a brief textbook. It is refreshing to find an author who is willing to admit that bacteria cannot be classed either as plants or as animals. A few suggestions for improvements might be made. An attempt to make a distinction between saprophytic and parasitic bacteria in the body is rather a waste of time, since it is necessary, as these authors have found, immediately to withdraw any such distinction. The acid alkali titration method might have been omitted, as it has been discarded for all practical purposes. An example of unnecessary detail is found in the description of the streptococcus groups. If the nurse can be taught to distinguish hemolytic and "green-producing" types, it is all that can be expected. The discussion of anaphylaxis is somewhat misleading. It is hardly correct to say that this phenomenon "explains why some people are left more susceptible to infectious diseases after one attack than ever before." It would have been desirable to make some further reservations in regard to the tuberculin test in order to prevent the inference that this test will diagnose the disease. The discussion of water purification is too casual to be of any value. The book is to be commended for its excellent illustrations.

Handbuch der normalen und pathologischen Physiologie mit Berücksichtigung der experimentellen Pharmakologie. Herausgegeben von A. Bethe, G. v. Bergmann, G. Embden und A. Ellinger. Band IX: Allgemeine Physiologie der Nerven und des Zentralnervensystems. (E.I.II. 1.2 a--c.) Bearbeitet von Ph. Broemser, E. Th. Brücke, usw., usw. Paper. Price, 78 marks. Pp. 840, with 162 illustrations. Berlin: Julius Springer, 1929.

In previous issues of The Journal since 1925, various volumes of this handbook have been reviewed as received from the publisher, some fifteen in all. The stupendous and commendable task is now nearing completion. In June, 1930, one volume (XVI) and parts of two others (XII/2 and XV/2) were still to appear in order to complete the set of seventeen volumes. It is the last word as a reference work and should be on the shelves of every biologic and medical library. The present volume deals with the general problems of the physiology of nerves and nerve centers, including such items as electrodiagnosis and therapy, metabolism of nerves, laws of stimulation, degeneration and regeneration, narcosis, local anesthesia, afterdischarge, summation, inhibition, reflex time, refractory phase, comparative physiology of the nervous system of the invertebrates, and conduction in plants. Most of the chapters will hardly interest the general practitioner. Even the clinical neurologist, unless himself doing research work in this general field, would find most of the matter too academic for his clinical needs although he fully realizes the importance of the collected data in the elucidation of the mode of action of nervous tissue.

Insomnia: How to Combat It. By Joseph Collins, M.D. Cloth. Price, $1.50. Pp. 130. New York: D. Appleton & Company, 1930.

Dr. Collins, through his experience as a neurologist, is able to look at the subject of sleep from the point of view of the mechanist concerned primarily with the physiologic functions of the body and of the psychiatrist who understands the deviations of the human mind. Hence his book may be considered one of the most practical works available in its field. His method of treatment includes not only proper attention to the physical accompaniments of sleep but particularly an attempt to get at the psychologic basis of the disorder that keeps the mind constantly in turmoil and distress. The book is essentially a new presentation of material published before. It carefully avoids much of the unestablished theory of modern psychologic schools. For this reason it is probably one of the most practical guide books available for those suffering with insomnia.

Medicolegal

Preformed Sac and Trauma in Relation to Hernia

(Berlau v. Metropolitan Life Ins. Co. (Kan.), 24 S. W. (2d) 686)

The Metropolitan Life Insurance Company issued to the plaintiff a policy insuring him against the results of bodily injuries caused by violent and accidental means but providing that it was not to cover disability caused wholly or partly by disease or bodily or mental infirmity. On or about Nov. 1, 1923, while the plaintiff was attempting to move a large iron safe, using a crowbar, he slipped and the upper end of the crowbar struck his left groin with sufficient force to cause him to fall. He suffered severe pains and was forced to discontinue work. When he examined his side, shortly after the accident, he found it bruised, discolored and swollen. After remaining at home for a day or so, he apparently returned to work and remained at his place of business for several months. January 9, the swelling caused him so much pain that he consulted Dr. I. J. Wolf, who diagnosed his ailment as an inguinal hernia and suggested an operation, which was performed, January 21.

The plaintiff instituted suit to collect under his insurance policy, and from an adverse judgment in the lower court the insurance company appealed to the Kansas City Court of Appeals. The company contended, among other things, that the hernia was the result of inherent physical weakness or defects or bodily infirmity and was therefore not covered by the policy. Dr. J. Park Neal, testifying as an expert for the company, stated that in all cases of inguinal hernia, particularly in the groin region, there is a congenital underlying cause consisting of a weakness of the abdominal structures and abdominal wall and lining. In such cases, he said, the canal does not fully close as it normally should and the peritoneum sags into this opening, forming a preformed sac. He testified, further, that in his opinion the fall described in the plaintiff's evidence could not have caused a hernia. Replying to a hypothetical question he said: "The hernia had to have the preformed sac. The strain may have forced some omentum or a piece of gut into the sac; I would not consider the blow had anything to do with it." On cross-examination he testified that hernia could be caused by a blow, but the blow would have to be such as to tear the abdominal walls and muscles and in such a case the man would be immediately disabled and in bed for weeks, or be compelled to undergo an immediate operation. The plaintiff testified that he had never had any trouble with hernia before the accident and that he had been examined by physicians for the insurance company, prior to the issuance of the insurance policy, and that they had found no evidence of hernia. Dr. Wolf, testifying for the plaintiff, in answer to a hypothetical question which recited the facts relative to the alleged injury, stated that such an occurrence could cause a hernia. With the conflicting theories presented by the witnesses, the court said, it is clear that the question as to whether the alleged hernia was due to the preformed sac, or whether it was due to the strain, the slip, blow or fall, was for the jury to determine and that the court was not authorized to disturb the findings of the jury in that respect.

The insurance company urged, also, that the evidence failed to prove that the hernia was produced by accidental means within the meaning of the policy, and cited the case of *Caldwell v. Traveler's, etc., Co.*, 305 Mo. 619, 267 S. W. 907, 39 A. L. R. 56. In the case cited, it was alleged that a surgical operation for two hernias resulted in an obstruction of the bowels and death. The court in that case reasoned that, assuming the obstruction of the bowels and the ensuing death were the unusual and unexpected result of the operation, skilfully done at the request of the insured, *intentionally* done, the death was not the result of accidental means. The court there held that where an unusual and unexpected result occurs by reason of the doing by the insured of an intentional act, where no mischance, mishap or slip occurred in the doing of the act itself, the ensuing injury or death is not caused through accidental means. In the present case, however, the court held that the alleged accident which caused the injury was unexpected, unforeseen and lay either in the slipping of the plaintiff or his fall against the crowbar, or both. Therefore, the court said, the ruling in the Caldwell case does not apply.

The policy provided that if an injury necessitated any surgical operation involving cutting into the abdomen for treatment of the organs therein, the sum of $100 was to be paid the plaintiff. The insurance company urged that the judgment of the lower court was excessive in that it allowed $100 for the herniotomy, contending that an operation for hernia does not require cutting into the abdomen. The court, however, overruled this contention. On condition that the plaintiff remit a certain sum, adjudged to be excess damages allowed by the lower court in computing the period during which the plaintiff was totally disabled, the appellate court affirmed the judgment of the lower court.

Wilful Betrayal of a Professional Secret

(McPheeters v. Board of Medical Examiners (Calif.), 284 P. 938)

The California Medical Practice Act provides that a license to practice medicine may be revoked for unprofessional conduct and includes in the definition of what constitutes unprofessional conduct "the wilful betraying of a professional secret." The board of medical examiners revoked McPheeters' license on the charge that he had been guilty of wilfully betraying a professional secret in that he wrote certain letters to a former office assistant in which he described operations performed on certain patients and imparted other information concerning the condition of the patients. The letters contained nothing which would in any manner tend to disgrace, embarrass or incriminate any of the patients and none of the patients made any objections whatever to the disclosures. The superior court, Fresno County, set aside the order of the board revoking the license and the board appealed to the District Court of Appeals, first district, division 1.

The phrase "wilful betrayal of professional secrets," said the court, cannot be held to apply to any and all disclosures that a physician may intentionally make. The statute is in its nature penal and is to be construed strictly in favor of an accused. By the use of the word "wilful" the legislature without doubt intended to mean an act that implied an actual and conscious infraction of duty and it would be a harsh and unreasonable construction to hold otherwise or to say that the disclosures here involved were of that character intended to be remedied by the statute. If such a construction was imperative, any disclosures, though harmless and innocently made without objection from the patients and regardless of their nature, would deprive a physician of his right to practice medicine, a right which has taken him years of study and a large expenditure of money to acquire.

Legislation of the character embraced within the general scope of the medical practice act, so far as it provides for the revocation of the certificate of a physician, can be sustained only on the ground that the legislature has authority under its general police power to provide all reasonable regulations that may necessarily affect the public health, safety and morals. The power thus conferred must be under provisions of law which are reasonable and declared with such certainty and definiteness that a physician may know exactly what they are. That the legislature did not intend the restriction to apply to all disclosures is evidenced by its use of the word "wilful." It has been held that such word means "deliberately and intentionally, and with design and purpose." *State v. Smith,* 199 N. W. 427, 159 Minn. 429, 511. It implies a deliberate intention, for which no reasonable excuse can be given, to do or refrain from doing some act which good faith in the performance of some duty requires or prohibits, as the case may be. It further implies that there must be some design, purpose and intent to do an injury. The word sometimes means "with a bad purpose and with the intention designedly and purposely to cause injury." So it has been held that an act, though intentional, is not wilful unless done with a wrongful purpose, or committed out of mere wantonness or lawlessness. *People v. Martinitis,* 168 App. Div. 446, 153 N. Y. S. 791; *Ex parte Cote,* 93 Vt. 10, 106 A. 519. It means "bad motive or purpose with the direct effect of injuring another" and involves the idea of premeditation and determination to do the act though known to be forbidden. *King v. Empire etc. Co.,* 148 Va. 585, 139 S. E. 478, 58 A. L. R. 193; *Gildersleeve v. Newton Steel Co.,* 109 Ohio St. 341, 142 N. E. 678.

The medical practice act was never designed nor intended, continued the court, to seal the lips of a physician against any and all disclosures, irrespective of their harmless character, nor was it designed to embrace facts not connected with the practice of a profession. The court affirmed, therefore, the judgment of the superior court, annulling the order of revocation made by the board of medical examiners.

Pharmacy: Care Required of Pharmacists.—For the treatment of his foxes, the purchaser ordered 100 tetrachlorethylene pills. Carbon tetrachloride pills were delivered to him instead and were administered to his foxes. As a result, eight died. In the suit that resulted, the court instructed the jury that:

> Ordinary care in reference to the business of a druggist signifies the highest practical degree of prudence, thoughtfulness, and vigilance, and the most exact and reliable safeguards consistent with the reasonable conduct of the business, in order that human and animal life may not be exposed to the danger flowing from the substitution of deadly poison for harmless medicine or more poisonous for lesser poisonous medicine.

The Supreme Court of Washington found no error in that instruction. It states the law, said the Supreme Court, in almost the same language as it is stated in *Willson v. Faxon, Williams and Faxon,* 208 N. Y. 108, 101 N. E. 799, 801, 47 L. R. A. (N. S.) 693, Ann. Cas. 1914D, 49, where it said:

> The negligence which must be established to render a druggist liable in such a case as this is measured by his duty; and, while this is only to exercise ordinary care, the phrase "ordinary care" in reference to the business of a druggist must be held to signify "the highest practicable degree of prudence, thoughtfulness and vigilance and the most exact and reliable safeguards consistent with the reasonable conduct of the business in order that human life may not constantly be exposed to the danger flowing from the substitution of deadly poisons for harmless medicines."

—Martin v. Bartell Drug Co. (Wash.), 284 P. 96.

Insurance, Accident: "Total Disability" Defined.—While there appears to be some conflict in the authorities as to what constitutes total disability within the meaning of an insurance policy providing for certain payments in case injury shall totally disable the insured, there is ample authority to be found both in the decisions and in the textbooks that in order to constitute total disability it is not necessary that the insured be absolutely helpless. An attempt by the insured to perform a few occasional, trivial acts relating to the duties of his employment, though in fact he ought not to have made such an attempt, does not deprive him of the right to show that he was totally disabled. It has been held sufficient to constitute total disability if the injuries are of a character and degree that common prudence requires the insured to desist from his labors so long as it is reasonable and necessary to effect a speedy cure.—*Sherman v. Continental Casualty Co. (Calif.), 284 P. 946.*

Insanity: Testamentary Capacity.—The word "incompetent," when used to describe a person's legal capacity to make a will, applies to any person, whether insane or not, who is by reason of old age or disease, or weakness of mind from any other cause, unable to understand what property he has, the relationship that he bears to those who would naturally be the objects of his bounty and what disposition he may be making of his property at the time. A person may be mentally incompetent to make a will and yet not be an insane person.—*In re Bielenberg's Estate (Mont.), 284 P. 546.*

Society Proceedings

COMING MEETINGS

American Society of Tropical Medicine, Cleveland, December 27-30. Dr. Edwin Peterson, U. S. Naval Hospital, Washington, D. C., Secretary.

American Student Health Association, New York City, December 29-30. Dr. D. F. Smiley, Cornell University, Ithaca, N. Y., Secretary.

Radiological Society of North America, Los Angeles, December 1-5. Dr. I. S. Trostler, 25 East Washington Street, Chicago, Secretary.

Society for the Study of Asthma and Allied Conditions, New York, December 6. Dr. Will C. Spain, 116 East 53d Street, New York, Secretary.

Society of American Bacteriologists, Boston, December 29-31. Dr. James M. Sherman, Cornell University, Ithaca, New York, Secretary.

Southern Surgical Association, Lexington, Ky., December 9-12. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.

Western Surgical Association, Kansas City, Mo., December 5-6. Dr. Frank R. Teachenor, 306 E. Twelfth St., Kansas City, Mo., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

Syphilis of Aorta and Heart.—Martland feels that, from a clinical and pathologic standpoint, syphilis of the aorta and heart should be regarded as an acquired disease (congenital cases being infrequent) developing insidiously and showing symptoms years after the initial infection. It is possible to recognize clinically and to diagnose an early aortitis, an aortic regurgitation, a narrowing of the coronary ostia, an aneurysm, or any combinations of these lesions. Treatment and prognosis should be based on such recognition. The myocardium in syphilis is frequently normal. When the aortic valve is involved, the main myocardial lesion is hypertrophy. Inanition atrophy is occasionally encountered. Specific lesions of the myocardium are infrequent, and, when they occur, are so slight in extent as to be of little practical importance. It is safer and better to assume that the coronaries distal to the aortic wall are usually normal in pure, uncomplicated syphilis, and that coronary occlusions, anemic infarcts, necrosis of heart muscle, replacement fibrosis, aneurysms of ventricular walls, and fibrous myocarditis are almost entirely due to coronary injury dependent on an arteriosclerotic process and have nothing to do with syphilis. That rheumatism and other infections may also produce forms of interstitial myocarditis is obvious. But it appears that syphilis does not play an important part in the production of such lesions.

Microscopic Pathology of Cardiac Syphilis.—Five cases of uncomplicated and probably untreated aortic regurgitation were studied microscopically by Maher. The inflammatory reaction, presumably due to syphilis, by exclusion of other factors was found to be a lymphocytic and plasma cell infiltration about the coronary arteries and their branches and beneath the visceral pericardium. In the muscular tissue the invasion appeared between the fibers and can be demonstrated about the capillary walls.

Localization of Syphilitic Virus in Aorta.—McMeans believes that in syphilitic aortitis the intima is involved primarily by direct infection from the blood stream. It may also be involved from the adventitia through the vasa vasorum. Histologically, the lesions are the same. Undoubtedly, the most serious lesions produced by syphilis on the aorta and heart are the syphilitic aortic endocarditis with regurgitation and occlusion of the coronary orifices. This is intimal disease. Therefore, it would appear that syphilitic intimal disease of the aorta is more important clinically than is medial disease.

Heart and Aorta in Acquired and Congenital Syphilis.—A series of fifty-four cases of acquired and twelve cases of congenital syphilis are presented by Kurtz and Eyster, with especial reference to the fluoroscopic observations in the heart and aorta. Fluoroscopic evidence of aortitis was found in 90.7 per cent of the cases of acquired syphilis and in 36.4 per cent of the cases of congenital syphilis. Aneurysm of the aorta was found in 18.5 per cent of the cases of acquired syphilis and was absent in all the congenital cases. Cardiac enlargement was present in 38.9 per cent of the cases of acquired syphilis. In a group of twenty-three cases of acquired syphilis, exhibiting primarily central nervous system disease, 95.7 per cent showed evidence of aortic involvement, and aneurysm could be demonstrated in 21.8 per cent.

Symptoms and Course of Syphilitic Aortic Insufficiency.—Scott made postmortem clinical observations in 107 cases of syphilitic aortic insufficiency. Syphilitic involvement of the aortic orifice may appear as early as five years and as late as forty-eight years after the primary infection. The average time interval is around twenty years. Free aortic regurgitation appearing out of a clear sky in an adult with a negative cardiac history, and with no evidence of acute infection, should be regarded as syphilis until proved otherwise. Substernal pain and anginal attacks are not important symptoms in the type of cases here considered. Syphilitic aortic insufficiency is more common in the Negro than in the white person. The appearance of congestive heart failure in a patient with syphilitic aortic insufficiency is a grave omen.

Diagnosis of Syphilitic Aortitis with Negative Wassermann Reactions.—In the forty cases of syphilitic aortitis reviewed by Levine, the Wassermann reaction in the blood was negative in twelve instances. There remained four cases in which there was no history of syphilis and no evidence of either aneurysm or aortic insufficiency. Such cases might be diagnosed in life by more careful roentgenologic study and by an occasional finding of a positive Wassermann reaction only after a provocative test, combined with other clinical data that in general point to syphilis.

Relation of Syphilis to Hypertension.—A group of 666 patients with essential hypertension was studied by Horine and Weiss to determine whether syphilis was a possible etiologic factor. A control group of 2,000 nonhypertensive patients of similar ages and economic status was studied. The incidence of syphilis was practically the same in the hypertensive group as in the control group. Syphilis cannot have any etiologic bearing on essential hypertension.

Cardiac Observations in Children with Congenital Syphilis.—In contrast to the conditions found in acquired syphilis, Previtali et al. were not able to detect, by available methods of physical examination, any cardiovascular lesion in the fifty cases of congenital syphilis examined.

Heart Disease in Children Due to Congenital Syphilis.—Four hundred and seventeen patients with congenital syphilis ranging in age from 3 months to 42 years were studied by Givan with reference to heart disease being caused by *Spirochaeta pallida*. Up to the present moment not one of the cases has shown signs or other collected data that would lead one to make a definite diagnosis of syphilitic heart disease.

Congenital Syphilis as Cause of Heart Disease.—McCulloch asserts that there is no evidence in this study that congenital syphilis contributes to the incidence of heart disease in children up to the age of 15 years. That heart disease and sudden death may follow this type of infection later in life is not made clear by this study, but it may be supposed that instances of this sequel would be about equal to those that follow other acute infections of childhood.

Intravenous Arsenicals in Treatment of Cardiovascular Syphilis.—A clinical study on the effect of neoarsphenamine on the symptoms of patients with cardiovascular syphilis is presented by Hines and Carr. Symptomatic improvement is believed to be a neoarsphenamine effect in 57 per cent of the cases. Twelve per cent showed aggravation of symptoms; probable anatomic damage was produced in three patients. No cases of sudden death or aneurysmal rupture were noted. A higher percentage of improvement is noted in patients who have syphilitic aortitis without definite aneurysm or aortic regurgitation. If the drug is cautiously administered in small doses, patients functionally classed 2 b (American Heart Association) may be benefited by the drug. Improvement in the serologic reactions of the blood does not always parallel the symptomatic improvement. Although the lives of patients with cardiovascular syphilis are perhaps prolonged by neoarsphenamine treatment, there is no evidence in any case studied which shows that the disease was permanently arrested.

Treatment of Cardiovascular Syphilis.—Moore and Danglade assert that the treatment of cardiovascular syphilis is best accomplished by a combination of such routine medical measures as rest, restriction of activities, and digitalis together with antisyphilitic treatment. An acceptable method of antisyphilitic treatment is based on the avoidance of therapeutic shock (the Herxheimer reaction) and the therapeutic paradox by starting treatment cautiously with bismuth compounds or mercury and the iodides, by the use of long courses of small doses of neoarsphenamine or bismarsen, and by the prolongation of treatment for a minimum of two years with alternation of these drugs. A study of forty-three patients with aortic aneurysm demonstrates that life may be prolonged from an average of nine months from the onset of symptoms in untreated patients, to an average of sixty-nine months in patients receiving one year or more of such treatment. A study of ninety patients with aortic regurgitation and eight with various other forms of syphilitic cardiovascular disease shows that life may be prolonged from an average of thirty-two months from the onset of symptoms in untreated patients to an average of sixty-five months in patients receiving one year or more of such treatment. These data seem to demonstrate that properly directed antisyphilitic treatment is of great value in cardiovascular syphilis.

Principles Underlying Treatment of Cardiovascular Syphilis.—Wile emphasizes the fact that the treatment of syphilitic heart disease is always a treatment of the individual patient. Such cases as are amenable to an antisyphilitic regimen respond well if not pushed too hard and if treated before decompensation has occurred or after it has been temporarily relieved. The mechanical end-results of syphilitic disease of cardiovascular nature are in no way influenced by antisyphilitic treatment. In those cases of cardiovascular syphilis in which benefit is achieved, this not only occurs because of dispersion of active processes in the affected part of the cardiovascular system but in a large measure is due to the dispersion of remote foci elsewhere in the body. Such foci in untreated cases must act as predisposing and contributory factors in the ultimate breakdown of the cardiovascular system. Fully compensated cases of cardiovascular syphilis which have a good background of early treatment are frequently cases which need not and should not be treated. Except for tryparsamide in certain selected cases of aortitis, better results are achieved by the conservative use of mercury, bismuth compounds and iodide than by the arsphenamines. These comments are not intended as dogmatic, incontrovertible statements of fact but are based entirely on personal experience.

Identity of Yellow Fever Lesions in Africa and America.—Klotz and Belt have found that the quality of the lesions arising in yellow fever in Africa is similar to that of lesions occurring in American cases. Furthermore, the incidence of various types of changes in different tissues is broadly the same, with differences only in a few reactions which may be accounted for by the technic applied. In these more careful studies, applied to a larger number of cases, they have confirmed their previous observations that the nature of the pathologic processes arising in the yellow fever of Africa is identical with that of such processes occurring in American cases. Variations that have been observed in the quality of the lesions here described are compatible with the variations that have been found in the case of different strains of virus isolated in America and in Africa.

*Hydrochloric Acid and Diarrhea. E. S. Emery, Jr., Boston.—p. 785.
Operative Treatment of Tuberculous Arthritis. C. F. Painter, Boston.—p. 787.

Value and Limitations of Spinal Anesthesia.—A report of the results following 2,302 administrations of spinal anesthesia is submitted by Deaver and Eckels which, together with a previous report, totals 4,553 spinal anesthesias from one clinic. The advantages and disadvantages of this type of anesthesia are discussed from a clinical point of view. A technic of administration that has proved practical and efficacious is given in detail. A graphic study of the blood pressure before, during and after anesthesia is incorporated. Two fatalities are reported.

Hydrochloric Acid and Diarrhea.—Forty-seven cases are reported by Emery which failed to show free hydrochloric acid on one or more gastric analyses. Ruling out those cases in which a true achylia gastrica probably did not exist, the incidence of diarrhea in this series is too small to justify the idea that an absence of hydrochloric acid is a cause of diarrhea. This is in accord with knowledge of intestinal disturbance in pernicious anemia and with a study of the stools. It seems more probable that the achlorhydria and the diarrhea are symptoms of the same condition.

Obstetric Cases at Minneapolis General Hospital.—A statistical survey of 7,226 obstetric cases, occurring during a five year period at the Minneapolis General Hospital, is presented by Adair and Sichel. There were 5,911 maternity cases in the series with 30 deaths, a mortality of 0.51 per cent. Puerperal sepsis was responsible for 43.3 per cent of these deaths. There were 1,272 abortion cases with 26 deaths, a mortality of 2.04 per cent. Sepsis was responsible for 84.6 per cent of these deaths. There were 46 extra-uterine pregnancies with 1 death, a mortality of 2.3 per cent. There were 5,483 recorded fetal presentations, with the occiput presenting in 96 per cent, the breech in 3.4 per cent, the face in 0.3 per cent, the brow in 0.05 per cent, and the shoulder in 0.25 per cent. Second degree perineal lacerations occurred in 8.7 per cent and third degree in 0.24 per cent of the series. Episiotomy was performed in 4.2 per cent. Forceps were applied in 3.3 per cent of the series, with a maternal mortality of 3.3 per cent and a fetal mortality of 7.5 per cent. Podalic version and extraction was performed in 0.93 per cent with a maternal mortality of 3.8 per cent and a fetal mortality of 45.3 per cent. There were twenty-six cases of placenta praevia treated, with a maternal mortality of 4 per cent and a fetal mortality of 46.1 per cent. There were twenty-nine cases of convulsive eclampsia treated, with a maternal mortality of 14 per cent and a fetal mortality of 52 per cent. The entire fetal mortality was 7.7 per cent. Of these, 2.9 per cent represented stillbirths and 4.8 per cent were neonatal deaths. By subtracting the seventeen previable stillbirths and the fifteen previable neonatal deaths, a corrected mortality rate of 2.6 per cent for the stillbirths and 4.5 per cent for the neonatal deaths is obtained, making a total corrected fetal mortality rate of 7.1 per cent.

Experience with Evaporated Milk in Infant Feeding.—Olmsted recommends the use of unsweetened evaporated milk in infant feeding because: It is entirely adequate from a nutritional standpoint when fed in conjunction with other foods and vitamins; it can be given in a concentrated state equivalent to whole cow's milk; it is easily digested; it is palatable, from the infant's standpoint; it is cheap and easily procurable. Personal experiences with this food are discussed.

Infantile Tetany.—Clein reports two cases in which active symptoms developed while viosterol was being given, for two and seven months, respectively. Both patients responded readily when the dosage was increased over that which they had been receiving.

*Abdominal Pregnancy: Case. A. W. Thrush, Chambersburg.—p. 37.
Cavernous Sinus Thrombosis. F. S. Mainzer, Clearfield.—p. 38.

Bilateral Cryptorchid.—Levin reports the case of a man, aged 33, with bilateral cryptorchidism. Neither testis was in the scrotum or inguinal canal. There was no evidence of eunuchoidism. The patient began to have coitus at the age of 17. He was reputed to have become, at the age of 28, the father of a child. For the past five years he had a psychosis (apparently a psychoneurotic depression), attended by great diminution in sexual desire and potency. When examined, at 33, the prostatic secretion did not contain spermatozoa.

Abdominal Pregnancy.—In Thrush's case the fetus developed to almost full term and was living at the beginning of labor. Fecundation presumably took place in some part of the left fallopian tube, which evidently ruptured, probably about the end of the third month, and the ovum with its sac intact escaped into the abdomen and became attached to the posterior and left external surface of the fundus of the uterus. Examination showed a loop of intestine probably 8 inches in length protruding from the vaginal orifice, which was replaced, and retained with a gauze pack. Dilation of the vaginal canal disclosed a tear in the vaginal wall on the left side, extending across the front of the uterus, well above the cervix toward the right to a point well beyond the median line. This tear, of course, was sufficiently large to allow the passage of the fetus. From the nature of this tear in the vaginal wall it was evident that the baby descended between the uterus and the bladder on the left side and that, during the passage of the head, the uterus must have been displaced to the right sufficiently to clear the canal of the pelvis and allow the head to descend. The patient had a fairly comfortable night. Continuous hypodermoclysis of salt solution was given under the left breast. The patient had no untoward symptoms on that day, but on the following day there was some distention of the abdomen. This slowly increased. Enemas failed to produce a bowel movement. The pulse became more rapid and wiry. There were several attacks of faintness. The temperature was normal with rises not exceeding 100 F. during the day. The patient gradually grew weaker and died about 100 hours after delivery.

Undulant Fever: Brucella Infection in Iowa. A. V. Hardy, C. F. Jordan, I. H. Borts and G. C. Hardy.—p. 2525.

Pharmacologic Action of Phenol Esters.—A pharmacologic study made by Smith et al. of the action of the phosphoric acid esters of phenol and some of the cresols has shown conclusively that triorthocresyl phosphate, and, so far as the present evidence goes, it alone, can produce in experimental animals a specific type of motor paralysis of the extremities in every sense comparable with that which occurred recently in human victims who drank of an adulterated fluidextract of jamaica ginger. Some of the differences in species susceptibility to triorthocresyl phosphate previously reported appear now to be due to differences in its absorbability from the alimentary canal. Certain other differences in species susceptibility cannot yet be accounted for on the basis of present limited knowledge of the manner of action of this poison in the animal body. Pharmacologic evidence has been presented to show conclusively that the adulterated fluidextract of jamaica ginger used for beverage purposes, resulting in an epidemic of partial paralysis, contained triorthocresyl phosphate to the extent of about 2 per cent. The chemical evidence secured confirms the pharmacologic evidence and fully harmonizes with it. The etiologic relationship of triorthocresyl phosphate to the recent epidemic of so-called ginger paralysis is thus definitely established.

Verruca Plantaris.—Sisk has made a study of fifty-three cases successfully treated by the roentgen ray. Three of the patients had had three treatments with electrodesiccation three months previous to roentgen treatment; they complained of pain with electrodesiccation and the result was unsuccessful. One patient had had one radium treatment of an hour's duration, without noticeable results. The surgical treatment has been observed in three cases; the result was satisfactory but the convalescent period was long and was associated with considerable pain and some disability. With the exception of two cases, pain was relieved after the fourth day following the first roentgen treatment and the convalescent period was about four weeks; the longest period was seven weeks, at which time all evidence of the growth had disappeared. The technic is a dose twice the time required to produce a mild erythema on the flexor surfaces, with unfiltered radiation limited to the bounds of the lesion, followed, if required, in three weeks by a dose of one and one-half erythema intensity. In only two cases was it necessary to give further irradiation—the greatest number of treatments was five in a single case. In none of the cases was there a period of disability. Many of the patients mentioned that the sites treated were slightly tender to pressure for a day or two, several days after the first treatment.

Radiography During Operation for Renal Calculus.—Willan asserts that radiography of an exposed kidney is a method that has come to stay. It is helpful in guarding against the recurrence of a stone. Detection of the exact site of a renal calculus by radiography is invaluable in preventing the needless sacrifice of renal tissue. Illustrative cases are given: (1) of a previously known renal calculus; (2) of an occasion when a uric acid stone was suspected but whose presence could not be proved prior to radiography of the exposed kidney; (3) of a man in whom, after supposed removal of all the calculi, a remaining stone was detected by radiography and removed; (4) of a sequel to a nephrolithotomy performed eight years before, the result being a functionless kidney owing to the extensive trauma at that operation.

Blood Calcium in Diabetic Retinitis.—Ten unselected patients with retinitis were examined by Lawrence and his associates. They were unable to detect any abnormality in the serum calcium contents of these patients. The average serum calcium of these ten cases was 9.6 mg. per hundred cubic centimeters; the lowest figure was 8.6, and the highest 11 mg. Seven cases fell between 9 and 10.5 mg., and in no case, therefore, was an abnormally low or high figure obtained. Five of the patients were males and five females. The average age was 61 years, the youngest being 44 and the oldest 71. Seven cases were severe enough to require insulin. The minimum ascertainable duration of the diabetes was two years, the maximum twenty years. Three patients showed traces of albuminuria without other evidence of Bright's disease; in them the retinal picture was that of diabetic retinitis alone. Gross arteriosclerosis was not a noticeable feature. The mean systolic pressure was 150 mm. of mercury, the diastolic 90; the highest systolic pressure was 185, the lowest 100. It is clear, therefore, that true Bright's disease and hyperpietic arteriosclerosis were not important etiologic factors in these cases, which appear to be really "diabetic" in nature.

Paste Bandage for Treatment of Varicose Ulceration.—The paste devised by the Cellan-Joneses contains the following substances in parts by weight: zinc oxide, 10; glycerin, 10; sterilized refined glue, 4; acacia, 5, and water, 30. When cold, this is a viscous medium which becomes much more fluid on warming. A sufficient quantity is placed in a double-jacketed basin and warmed by hot water. A bandage of requisite length and width is wound on one roller of the machine and carried through the basin, under a series of crossbars, to a second roller, where it is rewound after being thoroughly soaked in the warm paste. In this way a bandage impregnated with zinc oxide and possessing highly adhesive properties is produced. The bandages are wrapped in grease-proof paper and are stored ready for use in air-tight tins. They never solidify but remain soft, sticky and quite pliable, even when kept for months. No preparation is required before they are applied in the same fashion as ordinary cotton bandages.

Modification in Tracheotomy.—Russell proposes that tracheotomy should be preceded as a routine by an attempt at intubation of the trachea, with a view to rendering the operation easier and safer of performance; and that the nasal route should be chosen rather than the buccal, whether local or general anesthesia is employed. To this end it is urged that the tracheotomy set, which should have a place in every operating theater, should comprise a catheter suitably curved on a stylet, with a spray duly charged with cocaine; and that students should be shown the maneuver of nasal intubation—for example, during their period of anesthetic instruction. The acquisition of familiarity with this simple procedure should render a house physician's first tracheotomy a less alarming affair than it sometimes proves.

Etiology of High Blood Pressure.—Waller concludes that hypertension is due to the presence in excess of a specific amino-acid. This excess may be due to retention resulting from renal disease, to overproduction, or more probably to some impairment of hepatic function whereby this body is not efficiently destroyed.

*Septic Coronary Thrombosis with Myocardial Infarction, Embolic Infarction of Complete Kidney and Death from Uremia. A. A. F. Peel.—p. 168.

Septic Coronary Thrombosis.—The clinical features of interest in the case reported by Peel were: History of a mild infection associated with nasal catarrh, shivering and malaise. Four days later, sudden onset of symptoms suggesting myocardial infarction, which persisted for twelve hours in acute form. Recurrence of the cardiac symptoms after a further thirty-six hours with extreme disturbance of the peripheral circulation. While these symptoms persisted, supervention of tenderness in the right loin, absolute anuria, delirium, and evidence of uremia prior to death after thirty-six hours more. The pathologic conditions found (given in the order of the probable age of each lesion) were: Subacute diffuse nephritis. Septic endarteritis of a branch of the left circumflex coronary artery, with various stages in the formation of septic thrombi in its smaller divisions. Numerous areas of necrosis of the heart muscle, mainly periarterial, within the area of distribution of the affected vessel. Septic interstitial myocarditis limited to the area of distribution of the affected vessel. Secondary endocarditis of the overlying area of endocardium; intraventricular thrombosis. Embolus in right renal artery with complete infarction of right kidney; embolus in basilar artery. Congested, edematous brain. Generalized acute venous congestion. "Septic spleen." The cardiovascular system was remarkably free from degenerative pathologic changes in a man of his years (59), atheromatous changes being limited to one ulcer in the abdominal aorta, a few minute flecks of early atheromatous infiltration of the ascending aorta, and one or two similar flecks in the coronary arteries close to their origin; no evidence of arteriosclerosis either in the arteries or in the shape of preexistent renal disease of chronic type. On the other hand, the arteries showed an interesting congenital peculiarity, the medium-sized arteries being extremely thin walled and difficult to distinguish from the veins macroscopically, and the abdominal aorta being unusually narrow. This condition had not given rise to any symptoms during life.

Syphilis: Bismuth Therapy in Fournier's Clinic.—Schwartz describes the results obtained by bismuth therapy in more than 5,000 syphilitic patients during a period of ten years. The preparations of insoluble bismuth salts in oil suspension that were used during the first few years produced uniformly excellent results. Their action was not quite so rapid as that of arsenic but was fully as efficacious. In fact, lesions that had resisted treatment by arsenic and mercury yielded to bismuth. In addition to this, the bismuth treatment caused none of the dangerous reactions that are likely to follow the injection of arsphenamine. However, the insoluble bismuth salts were not so rapid in their action as arsphenamine, their absorption was sometimes irregular, and the results were hard to regulate because of the impossibility of accurate measurement of the quantity of metallic bismuth in the suspension. Fournier and Guenot endeavored, therefore, to perfect the method so as to eliminate these difficulties. The result of their efforts was the development of the use of bismuth salts soluble in oil or liposoluble bismuths. These preparations are as rapid in their action as arsphenamine and have a more constant and lasting serologic action. Bismuth resistance has not been observed in any of the patients so treated in the clinic, and the results have been highly successful. The method now employed is that of intramuscular injections of 2 cc. of oil solution containing an equivalent of 0.08 Gm. of metallic bismuth, from ten to twelve injections usually being sufficient. The first three injections are given every two or three days and the later ones twice a week.

*Electrocardiographic Anomalies in Infectious Diseases. A. Clerc and R. Levy.—p. 1257.
*Spasm of Oddi's Sphincter as Cause of Jaundice. I. Nanu-Muscel and I. Pavel.—p. 1260.

Electrocardiographic Anomalies in Acute Infectious Diseases.—Clerc and Levy are convinced that the anomalies revealed by electrocardiography in infectious diseases are worthy of serious consideration both as a confirmation of anatomic and clinical observations and for their independent semeiologic and prognostic value in cases in which more obvious manifestations are lacking. For instance the elongation of the P-R interval in a severe case of endocarditis showed the existence of acute rheumatism, although there was no evident arthralgia; medication with salicyl compounds gave good results. While the results thus far obtained have not determined the exact future indications in the various electrocardiographic anomalies observed, they have shown that conditions may be revealed in this way even when the physical examination is negative and that the persistence of the anomalies may have marked significance.

Spasm of Oddi's Sphincter as Cause of Jaundice.—Nanu-Muscel and Pavel describe two cases in which chronic jaundice was caused by a spasm of Oddi's sphincter due to pancreatic disturbances. In the first case, the primary infection was a chronic pancreatitis, in the second it was a cancer of the head of the pancreas. In the latter case, although the cancer itself might later have caused the jaundice, the spasm of the sphincter occurred before the cancer was sufficiently developed to constitute a mechanical obstacle. From the therapeutic standpoint, a purely medicinal treatment to counteract the original infection is usually sufficient. In the first of the cases described the patient was cured by intravenous injection of methenamine and sodium salicylate. The authors are convinced that a reflex spasm of Oddi's sphincter is the direct cause of a great many cases of chronic or prolonged jaundice both when no mechanical obstruction can be determined, as in the case of chronic pancreatitis which they describe, and as a preliminary or a coexistent functional obstacle when there is also a mechanical obstacle present.

Diabetes: Bouchardat's Diet. ,F. Maignon.—p. 1280.

Parenteral Hepatotherapy in Anemia.—The classic method of hepatotherapy, that of eating raw liver, produces excellent results in the treatment of anemia. However, several weeks of treatment is usually necessary before much amelioration is perceived, which is disastrous in many severe cases. Extract of liver taken by mouth often causes serious digestive disturbances and can rarely be tolerated by a patient for more than a few days. Achard and Hamburger gave intramuscular injections of liver extract in several cases with good results. This method permits the initial injection of quantities of extract far superior to the amount of liver that could be taken orally; its action is therefore more rapid. The organism also seems to absorb the extract more rapidly when so administered than when it passes through the digestive tract. The only objection to the method of intramuscular injection is the fact that painful cutireactions often occur that necessitate discontinuing the treatment. To avoid this the authors tried giving intravenous injections instead of intramuscular ones. While the patient tolerated the injections perfectly, the amelioration thus effected was only temporary. However, the intravenous method has not been given a systematic trial and might prove more successful. At any rate, intramuscular injection has proved itself to be valuable as a treatment of attack to bring immediate results, and if the patient should find that the injections are too painful, the classic method may be resumed when the cure is under way.

Digestive Troubles from Artificial Pneumothorax.—The digestive troubles often observed in connection with an artificial pneumothorax are sometimes localized in the stomach, intestine or liver, and are sometimes general. In cases of gastric localization the patient begins to eat with good appetite but his stomach soon feels full, painfully enlarged and heavy. Often the discomfort is increased when he is in a recumbent position. Vomiting also occurs frequently. In a few cases the reaction may be caused by the purely mechanical action of the pressure of the diaphragm on the gastric organs. However, Bonafé and Mollard believe that in most cases it is due to a reflex associated with a condition of aerophagy. In the intestinal tract, the chief manifestations noted are diarrhea and symptoms of tuberculous enteritis. These are not, however, the direct result of the pneumothorax; the infections were already present and their appearance was merely accelerated by the operation. The hepatic disturbances that are observed in rare instances are undoubtedly caused by the purely mechanical action of the lowered diaphragm. Often instead of a localized reaction the patient merely loses weight and feels a general loss of appetite, which is undoubtedly caused by the interruption of the normal function of the lungs in lipodieresis and neutralization of toxins. All these digestive disturbances are benign and disappear within a few weeks. They are, therefore, in no way an argument against the use of the pneumothorax.

Morphologic Type of Resistance to Pulmonary Tuberculosis. A. Jacquelin. —p. 1289.
*Ambulatory Treatment of Diabetes for General Practitioner. J. J. de Jong.—p. 1292.

Ambulatory Treatment of Diabetes for General Practitioner.—De Jong describes a treatment of diabetes that can be used by any physician and that permits the patient to continue his normal life. It consists merely of a simple diet to reduce the glycosuria. The initial daily ration is 200 Gm. butter and 1,000 Gm. legumes (1,700 calories). In addition, he sanctions coffee, tea, mineral water and red wine. The patient comes to the clinic for urinalysis every few days. When the glycosuria has disappeared, as should be the case within two weeks, one egg or 50 Gm. of potatoes is added to the diet. In a few days, if the potatoes were chosen, an egg is added or vice versa. Then an additional 50 Gm. of potatoes and a second egg are included. The daily diet is thus 1,000 Gm. of legumes, 200 Gm. of butter, 100 Gm. of potatoes and two eggs, a total of 1,962 calories. This diet is generally reached in three weeks. If the patient remains aglycosuric, the writer adds 20 Gm. of bread and 25 Gm. of cheese. Little by little, fruits, meat, fowl, fish and lard are added and at the same time the quantity of legumes and butter is diminished, until after several weeks the patient has an adequate and varied diet at his disposal. This treatment is manifestly impossible in cases that show complications such as tuberculosis or infections of the heart, which require special clinical care. The patient should moreover be most carefully watched during the first two weeks; if at the end of that time glycosuria still persists, insulin treatment is probably necessary. However, many chronic cases of diabetes may be successfully relieved by this means, especially if the physician explains the nature of the disease to the patient, so that he understands the importance of strict adherence to the prescribed diet.

*Single Congenital Ectopic Hydronephrotic Kidney. A. Marsella.—p. 495.
*Significance of Aberrant Renal Vessels for Pathogenesis of Uropyonephrosis. V. Lozzi.—p. 515.

Roentgen Examination of Tuberculous Kidney.—Rinaldi points out that there are many anatomic varieties of renal tuberculosis and that arteriography will reveal only a stenosing panarteritis, which gives no precise information. To pretend that arteriography will permit the roentgen demonstration of all tuberculous lesions of the kidney is absurd. Possibly the Dos Santos method will show whether the functional deficit, so early observed in tuberculous kidney when the specific lesions are still slight, is the consequence of an advanced arterial insufficiency of the kidney itself. It is possible that the future will change totally the practical interest of this new method of examination, so that it will give early an exact picture of the circulatory modifications of a diseased viscus. But it will not replace the functional examination of the urine, which, with all its causes of error, with all its possible variations, and, above all, with its strict requirements as to precision, technic and patience, will remain the classic means of diagnosis in urinary tuberculosis.

Single Congenital Ectopic Hydronephrotic Kidney: Two Cases.—Marsella says, with regard to the treatment of such a kidney, that the mere fact that the kidney has an abnormal location is not in itself a justification for surgical intervention. If the kidney is functioning normally in its abnormal position, it should not be disturbed. However, cases have been reported in which a pelvic kidney was a hindrance to pregnancy and was the cause of repeated abortions. In such cases, it is advisable to try to place the kidney in a higher position—in the vicinity of the iliac crest, if possible—but it is usually firmly fixed and does not lend itself to removal owing to the shortness of the vessels. If the kidney is a hindrance to the completion of the birth act, it is an indication for cesarean section.

Significance of Aberrant Renal Vessels for Pathogenesis of Uropyonephrosis.—Lozzi brings out that in all his cases the anomalous vessel must be regarded as the primary cause in the genesis of the hydronephrosis. It is established, however, that there was also a slight degree of exaggerated renal mobility. Treatment should be applied as early as possible, and depends on the anatomofunctional state of the kidney. In incipient cases it will suffice to resect the vessel, eliminate the adhesions if any, and fasten the kidney in a favorable position. Fixation alone does not suffice, as has been shown in numerous cases of other authors, and as was shown in two of Lozzi's cases. In cases of advanced uronephrosis or uropyonephrosis, it is necessary to resort to nephrectomy, which was done in eight of the author's cases. The results secured were good in nearly every instance. The remote results in the cases in which it was possible to get exact information have been more than satisfactory, the clinical recovery having been maintained.

Hypertonic Solutions of Dextrose in Treatment of Acute Peritonitis. R. Lombardi.—p. 1310.
*Gastric Leukodiapedesis. U. Santomauro.—p. 1313.

Gastric Leukodiapedesis.—The phenomenon of leukodiapedesis has been generally observed in many different mucosas and variously interpreted. Santomauro conducted a series of experiments on dogs by means of microscopic examination to determine the nature of gastric leukodiapedesis as a phase of the general phenomenon of leukodiapedesis. From these experiments he draws the following conclusions: In different stages in the digestion of meat the number of leukocytes passing through the mucosa is always less than during a period of fasting. Experimental conditions that logically cause an irritation in the mucosa cause transmigration of a still greater number of leukocytes than is observed during either digestion or fasting. The phenomenon of gastric leukodiapedesis, therefore, seems to the author to be linked not so much with the specific digestive function of the mucosa as with more general functions of defense or resistance. These conclusions are in direct contrast with those presented by Marchal in 1925, who claimed that gastric leukodiapedesis was directly connected with the digestive function.

*Antagonism Between Epinephrine and Ergotamine, and Respiratory Exchange. R. Capo.—p. 1347.
Biotypologic Ceco-Appendicular Semeiography. W. Berardinelli.—p. 1353.
*Echinococcus Cysts of Thyroid. G. Sabatini.—p. 1357.
How Can Epithelium of Renal Pelvis Be Recognized in Urinary Sediment? E. U. Fittipaldi.—p. 1360.

Antagonism Between Epinephrine and Ergotamine, and the Respiratory Quotient.—Capo experimented to discover whether ergotamine will counteract the increase of energy exchange caused almost constantly by epinephrine, whether administered fasting or after the ingestion of food (dynamic-specific action). From his researches, he concludes that ergotamine does not modify the greater consumption of oxygen induced by epinephrine but that it does cause, when administered fasting, a notable lowering of the elimination of carbon dioxide and a reduction of the respiratory quotient. His study of the gas exchange demonstrated the antagonistic action that these two substances exert on carbohydrate exchange. Epinephrine causes a mobilization of hepatic glycogen and thus increases almost constantly the elimination of carbon dioxide and raises the respiratory quotient. Ergotamine, on the other hand, inhibits the hyperglycemia that is induced by the epinephrine without modifying the increased intra-organic combustion caused by epinephrine. In other words, under the action of ergotamine, epinephrine, though glycogenolysis is checked, stimulates the cells to a greater combustion, and these cells, not having sufficient carbohydrates at their disposal, burn other reserve substances, namely, the fats, thereby lowering the respiratory quotient.

Echinococcus Cysts of Thyroid.—Sabatini describes a case of echinococcus cysts in a man, aged 21, who came with a diagnosis of cystic goiter. The intervention revealed about thirty hydatid cysts, buried in pus, whose presence explained the pain and the rapid growth of the tumor. Thick and tenacious adhesions, provoked by the suppuration of the cysts, necessitated marsupialization. The patient recovered completely.

Mechanism of Liver Diet in Pernicious Anemia.—Duesberg states that during pernicious anemia the blood does not contain methemoglobin. However, when liver therapy is instituted methemoglobin appears in the blood and, following this change in the decomposition of the blood pigment, regenerative processes set in. Therefore it was assumed that the active substance in the liver is a producer of methemoglobin. This substance causes a disintegration of the immature erythrocytes by changing hemoglobin into methemoglobin. The methemoglobin, or substances that are formed simultaneously with it, stimulate the bone marrow to such an extent that it changes its action and again produces normal erythrocytes that have a greater resistance. As experiments *on healthy persons* indicate, these erythrocytes likewise disintegrate quickly; however, if sufficient liver is given, *formation and disintegration* are in equilibrium. Observations on patients and the results of experiments *on animals* could be substantiated in experiments in vitro. In all liver preparations examined there existed a *substance that* formed methemoglobin in vitro. The greater the purity and the concentration of the liver preparation, the more rapid was the change of hemoglobin into methemoglobin. The preparations of desiccated stomach, which recently have been used with good effect in cases of pernicious anemia, contain the same active substance as liver. Meat has the same effect on the blood status in pernicious anemia if it is first treated with the gastric juice of healthy persons. It has also been found that the hematologic symptoms in patients with pernicious anemia could be improved when normal gastric juice was introduced. Tests revealed that the substance is not present in pernicious anemia but is present in normal persons.

Influence of Hormone from Anterior Lobe of Hypophysis *on* Hypogenitalism.—Schapiro describes the effects that he obtained with a hormonal preparation of the anterior lobe of the hypophysis. *The preparation contained* 100 rat units per ampule. It was employed on twenty-six male patients with *hypogenitalism*. *The author* classifies the patients into four groups. To the first group belong the eunuchoids of the slender type. There were six men *ranging in age from* 19 to 29. To the second group belong patients with genital hypoplasia, adipositas and decreased specific dynamic action. There were fifteen children ranging in age from 9 to 18 and one man aged 27. To the third group belong patients *with* infantilism in the sense of a generalized arrest in the development; in this group there were two children aged 14 and 18. To the fourth group belong those with cryptorchidism; in this group there were two children aged 12 and 16, respectively. Cryptorchidism was also observed in eleven cases of the first three groups. In describing the growth effects of the treatment, the author differentiates between three degrees of maturity. As the first degree of maturity he considers beginning growth of the testes and penis, increase in the pubic hair and in the axillary hair, and in cryptorchids a partial descent of the testes. As the second degree of maturity he considers complete descensus, enlargement of the testes and penis but not yet to normal size, and there is not yet a production of semen. Third degree maturity is complete sexual maturity and the presence of living spermatozoa in the ejaculate. A maturity of the first degree developed in all twenty-six cases; in fourteen instances a maturity of the second degree was noted and in nine cases a complete maturity resulted. The *best results* were obtained in those persons who were near the age of puberty. The hypophyseal extract also influences the gas metabolism. The specific dynamic action is increased and in most cases also the basal metabolism. It is probable that the typical slender eunuchoidism is not always primarily of a genital origin but is often due to hypophyseal disorders.

Newer Methods for Determination of Paternity.—Mau points out that in recent years new methods have been devised for the determination of paternity. In the first part of the article he discusses dactyloscopy, which has been used widely in criminology. It is known that the finger prints of an individual are never identical in all details with the finger prints *of another person*. However, it has been noted that between the finger print patterns of parents and children there is a certain *resemblance*. The author discusses the characteristics of the four main types of finger prints and shows their significance in the determination of paternity. He comes to the conclusion that dactyloscopy is as yet not entirely satisfactory for the determination of paternity. In the second part of the article, several blood tests are evaluated. By means of the test based on the heredity of the blood groups it is not always possible to detect the father of a child; however, if a man has a blood group that has no relation to that of the child, he cannot be the father. The author further describes Zangemeister's method. In this test a decrease in the light permeability can be detected with the step photometer, when the serum of the child is mixed with that of the father. However, when the serum of another man is added to that of the child the decrease does not become manifest. According to Zangemeister the reaction is due to the fact that during pregnancy, as a result of the presence of the paternal sperm protein, antibodies are formed in the blood of the mother and of the child. The reduced light permeability that results when the serums of father and child are mixed is due to the presence of these antibodies. Regarding the practical value of Zangemeister's serologic method, the author states that although Zangemeister himself has always obtained positive reactions, he and several other investigators have found the test not entirely reliable. Further tests will be necessary to determine whether Zangemeister's reaction will be a reliable method for the determination of paternity.

Symptomatic Fulminant Purpura in Meningococcus Sepsis.—Seeber describes the case of a girl, aged 15, in whom *purpura* was only a symptom of a generalized disease. A severe meningococcal infection was the cause, and it may be assumed that a congenital hypersensitivity of the patient's skin increased the tendency to bleeding. The case ended fatally within twenty-four hours. Microscopic examination revealed the severity of the infection. Pathogenic micro-organisms were found in nearly all the organs. The *term symptomatic* fulminant purpura applies to infections with a foudroyant course and which are accompanied by symptomatic, hemorrhagic diathesis.

Clinical Aspects and Diagnosis of Hypophyseal Cachexia.—Herman reports the case of a woman, aged 48, who was anemic and cachectic. She complained of lack of appetite and of vomiting. On the basis of these symptoms, cancer of the stomach was assumed; however, the roentgen examination did not verify the diagnosis. The Wassermann reaction was negative, the blood picture did not indicate pernicious anemia, and there were no signs of parasitic infestation. Then lymphogranulomatosis of the retroperitoneal lymph nodes was thought of and also hypophyseal cachexia. In consideration of the possibility of these two conditions, the woman was again thoroughly examined. Decayed teeth and a high degree of psilosis were discovered. There was no axillary hair, and the pubic hair was scanty. The sella turcica was normal. The author points out that gastric disorders, cachexia, anemia, decaying teeth and deficient hair growth are found in hypophyseal cachexia and on the basis of these symptoms he diagnosed the case. He instituted a substitution therapy by giving a hypophyseal preparation and also administered hydrochloric acid. As a result of the treatment the gastric symptoms disappeared and the woman's general condition improved considerably. In the conclusion it is pointed out that whenever gastric, hematologic and endocrine symptoms concur, hypophyseal cachexia should be thought of.

Roentgen Irritation-Therapy of Subacute or Chronic Genital Diseases in Female.—Seitz's experience includes 380 cases in which irritation doses of roentgen rays were applied for treatment of an inflammation of the genitalia. Fourteen of the women were affected with parametritis; the remainder with adnexitis or with pelviperitonitis. The irradiation (180 kv.) was applied to an abdominal field 20 by 24 cm. The rays were filtered through 1 mm. of copper and 1 mm. of aluminum. From 15 to 20 per cent of unit skin doses were applied to the skin, and from 4 to 6 per cent of unit skin doses penetrated into the pelvis. The dose of roentgen rays reaching the ovaries did not exceed from one sixth to one eighth of the castration dose and therefore was considered as harmless. In most of the cases the irradiation was used once; in a few cases it was repeated one or two weeks later. Exceptionally a third irradiation was required. The roentgen therapy was combined with the usual conservative measures as, for instance, hot air, hot irrigations or diathermy. In 77.9 per cent of the patients with adnexitis or pelviperitonitis, a considerable improvement of the subjective and of the objective signs was noted; in 11.7 per cent, the subjective signs alone were favorably influenced. In the remainder (10.4 per cent) the treatment was without effect. The results of the treatment proved to be the same whether the adnexitis was of gonorrheal or of septic origin, as after abortion or puerperal fever. The improvement was always accompanied by reduction of the leukocytosis and by retardation of the accelerated sedimentation of the erythrocytes. Both reactions were most pronounced in cases of gonorrheal adnexitis. In all cases of acute parametritis the roentgen therapy promoted the resorption process or accelerated the formation of an abscess. The author stresses that in cases of acute gonorrheal adnexitis the treatment should be either avoided or used with extreme caution.

Roentgen Therapy in Case of Myeloid Leukemia.—Hammerschlag and Knospe report the case of a woman, aged 35, who was admitted to the hospital with a presumptive diagnosis of an ovarian tumor. On examination, the genitalia appeared normal; the abdominal tumor proved to be an extremely enlarged spleen descending into the small pelvis. Blood examination pointed to a typical myeloid leukemia; the number of leukocytes was 255,000, with a predominance of myeloblasts. On account of the poor general condition, extirpation of the spleen was excluded and roentgen therapy was tried. One third of a unit skin dose was applied to a field 10 by 15 cm. About 190 kv. and 2 milliamperes were used for the irradiation, with a zinc filter of 0.5 mm. and an aluminum filter of 1.0 mm.; the focus-skin distance was 40 cm. The irradiation was well tolerated by the patient. On the fourth day after the irradiation, the fever disappeared; the general condition improved. The number of leukocytes became reduced to 88,000; the blood picture approached normal. On the eighth day, the size of the spleen decreased; its lower border could be perceived beneath the umbilicus. After a sojourn of two weeks in the hospital, the patient was discharged. She was readmitted to the hospital a year later. On blood examination, 120,400 leukocytes and a predominant number of myeloblasts were found. The spleen reached the upper edge of the pubic symphysis. The irradiation was renewed (the same dose of rays as the first time); within fourteen days the number of myeloblasts decreased and that of the leukocytes was reduced to 70,000. The size of the spleen became smaller by three fingerbreadths. Up to the present, the irradiation has been twice repeated. During the two years of treatment, the patient was able to do housekeeping. It is expected that, by continuing the treatment, the improvement of the patient may persist.

Practical Value of Spirometry in Pulmonary Tuberculosis.—Kutschera-Aichbergen shows that spirometry, or the determination of the vital capacity, is a valuable aid in determining the functional capacity of the lungs. First he defines vital capacity and describes the technic of spirometry. Then he explains the formula according to which the normal vital capacity may be estimated. Whenever spirometry reveals a marked reduction of the normal vital capacity, a pathologic condition exists. The author further describes the vital capacity in pulmonary tuberculosis. Tuberculous changes in the lungs, especially exudative processes, reduce the vital capacity. Because the technic of spirometry, as well as the required apparatus, is so simple, the general practitioner can easily make use of it. This method facilitates the diagnosis of the exudative early forms of tuberculosis, the early infiltrate and its sequelae. A comparison of spirometric tests makes it possible to determine the further dissemination, or the progress in the cure of the tuberculous process, without the aid of a roentgen apparatus. However, it is interesting and instructive to compare the results of spirometric tests with the roentgenograms. In cases of phrenic avulsion, pneumothorax and other forms of collapse therapy the determination of the vital capacity indicates their encroachment on the functioning of the lungs.

Etiology of Articular Rheumatism.—Risak points out that recently several authors have reported observations that again bring into prominence the question of the bacterial pathogenesis of articular rheumatism. Reitter and Löwenstein assume a tuberculous origin. The author describes the results of examinations of the exudates from the joints of patients with rheumatic polyarthritis. The bacteriologic tests always gave negative results, the staining tests as well as the cultures. Several animal experiments likewise gave negative results. The author further reports the clinical history of a patient in whom, besides old and new tuberculous processes in the lungs, there also existed a tuberculous lymphadenitis. The anamnesis and the clinical observations indicated that a rheumatic polyarthritis existed simultaneously with, but independent of, the tuberculosis. Two other cases are reported in which a polyarthritis developed in connection with a tonsillitis. However, the author sees no definite proof for the assumption that bacteria caused the exudates in the joints. The clinical aspect in these cases spoke against a bacteriologic pathogenesis. In the conclusion the following statement is made: The fact that, in rare cases of polyarthritis, bacteria can be found in the exudates of the joints, does not justify the assumption of a bacteriologic pathogenesis for all cases.

Advisability of Extirpation of Spleen in Pernicious Anemia.—Spengler gives the case reports of two patients with pernicious anemia in whom the spleen had been extirpated. In both instances a remission lasting eleven and ten years, respectively, was effected. Observations on the splenectomized patients prove that the liver and the spleen have an antagonistic action in the regulation of the erythrocyte content of the blood. Because of the good results that recently have been obtained with liver diet and with desiccated hog stomach, it would not be advisable to abandon these treatments in favor of splenectomy with its comparatively high operative mortality (20 to 30 per cent). However, in cases in which liver diet and stomach powder do not bring the desired results, splenectomy may be resorted to. The two cases reported prove that extirpation of the spleen is of therapeutic influence not only in cases of familial hemolytic icterus but also in pernicious anemia.

Exclusion of Kidney by Roentgen Irradiation.—Halbfas-Ney reports a case of left-sided pyonephrosis in a woman, aged 59, who had previously had numerous attacks of pyelitis. Because of the poor general condition of the patient (myocarditis, high blood pressure and chronic bronchitis), nephrectomy was deemed too dangerous. Therefore a nephrostomy was performed under local anesthesia and a large amount of pus was evacuated. Two rubber drains were then introduced. The operation was followed immediately by a return of the temperature to normal. Six days later the patient felt better and the drains were shortened. Two days later they were removed and a gauze strip was introduced. Through the fistula there passed a large amount of urine. To stop the discharge of urine, two roentgen irradiations were given. In the first irradiation, 100 per cent of a unit skin dose was applied to the lumbar region over an area of 8 by 8 cm. and through a zinc filter 0.5 mm. thick and an aluminum filter 1 mm. thick at a focal distance from the skin of 23 cm. Two days later, 90 per cent of a unit skin dose was applied to a ventral field in the region of the kidney with the same filters and the same focal distance. After the irradiations the secretion of urine increased markedly for eight days and then began to diminish; after a few days more it stopped completely. This form of treatment of pyonephrosis is to be recommended particularly in debilitated patients who could not survive a nephrectomy. The preliminary nephrostomy permits unobstructed drainage of the pyonephrosis and by eliminating the flow of toxins to the other kidney facilitates its return to normal. The dense adhesions produced about the pyonephrotic kidney by the drainage and irrigation of the pus sac render its removal difficult and dangerous. Under such conditions the treatment of choice is exclusion of the kidney by roentgen irradiation.

Chorio-Epithelioma of Testis.—Scheftel reports a case of chorio-epithelioma of the testis with a metastatic growth the size of a child's head originating in the mesenteric lymph nodes and adherent to the small and large intestines. In the tissue of both lungs there were numerous grayish red tumor nodules; the entire lower lobe of the right lung had been replaced by tumor tissue. Metastatic nodules in the neighboring lymph nodes had invaded the vena cava, the portal vein and the right ureter. Emphasis is laid on the rapidity with which chorio-epitheliomas destroy the blood vessels and give rise to metastases and on the resulting importance of an earliest possible diagnosis and surgical treatment. Roentgen rays and radium should be used only as adjuvant treatment to prevent lymph node metastases.

Blood Pressure During Epileptic Seizure.—Hendriksen studied the blood pressure of thirteen persons during sixteen epileptic seizures. In two instances the patient had status epilepticus, in two the seizure appeared spontaneously and in twelve it was induced by hyperventilation. It was noted that the epileptic seizure is always accompanied by a rise in the systolic blood pressure, whereas the diastolic blood pressure and the pulse are affected but little. In rare instances the rise in the blood pressure may be demonstrated some minutes before the attack, but most often it comes on immediately before the attack; it sets in suddenly and reaches its maximum in the beginning of the attack. The end of the attack is accompanied by an equally sudden fall in the blood pressure. When the seizure is over the blood pressure has usually reached the same value as before the attack and it remains at this level.

Intracranial Pressure: Determination by Bailliart's Method of Ophthalmodynamometry.—Winther describes Bailliart's ophthalmodynamometer and states that it is used thus: The instrument is placed on the eyeball and the intra-ocular pressure is increased while at the same time the central artery of the retina, which normally does not pulsate, is viewed through the ophthalmoscope. By a progressive augmentation of the pressure one sees first that the artery begins to pulsate and then, when the pressure is increased still more, the pulsations disappear. The appearance and disappearance of the pulsations represent, respectively, the diastolic and systolic pressures of the central artery of the retina and these constitute an index of the intracranial pressure.

PREGNANCY AND TUBERCULOSIS

A STUDY OF THE OBSTETRIC HISTORIES OF FOUR HUNDRED AND EIGHTY-FOUR PATIENTS *

HARVEY B. MATTHEWS, M.D.
BROOKLYN
AND
LOUISE STEVENS BRYANT, Ph.D
NEW YORK

Since tuberculosis appears not to be diminishing as rapidly among girls and young women as it is in other age and sex groups, the combination of tuberculosis and pregnancy will continue to be a critical phase in preventive medicine. It was to remedy the lack of case material in this field and to assemble whatever facts could be obtained from a selected group of tuberculous women in relation to pregnancy that the present study was undertaken.

Each year on the anniversary of the patient's "graduation" from Trudeau Sanatorium, he reports on his present status. In 1925 and 1926, through the courtesy of the medical board, and in cooperation with the superintendent, Dr. Fred H. Heise, additional forms were sent out to 1,000 married women graduates, inquiring as to their experience with child-bearing. Nearly half responded, 484 in enough detail to make possible certain comparisons and observations, which are here presented.

The replies were intelligent and painstaking, as was to be expected from a group made up of well educated women, most of whom were high school, and a large proportion college, graduates.

GENERAL OBSERVATIONS

In the absence of mortality figures, the less dramatic measures of effort, waste and achievement under handicap must be used.

The outstanding fact, and the important one for the community, is that these women are not contributing in anything like their proportions to the coming generations. Certainly they cannot be described as reckless breeders.

One third of the 484, or twice the highest figure set for involuntarily sterile marriages, never became pregnant. (Estimates for involuntarily sterile marriages range from one in six to one in ten.) The other two thirds proceeded with caution. They became pregnant only about half as frequently as the average, if the women attending birth control clinics can be taken as the average. Finally, they brought to living birth a far smaller proportion of the children conceived than appears usual. Just over half of the group, 287, bore even one living child, and these bore a scant two apiece.

Those who bore more than one or two living children had done so before contracting tuberculosis. Losses before and immediately after birth were disproportionately high, averaging thirty-five to every hundred living births, as compared with nineteen to a hundred among the clients of birth control clinics. But losses after birth were extremely infrequent. Most of the babies were breast fed and kept on a careful regimen, and nearly all were given medical examination, so that only a third of the expected number died in infancy, and few indeed thereafter. Of the 579 children born alive, 556 were still alive when their mothers reported, fifteen years later.

Reports on the present condition of the children were monotonous: "healthy," "robust," "normal" were used to describe nine out of ten. The tenth child was described as "thin," "undernourished," "subject to colds," with an occasional "nervous"; but few serious handicaps of any sort were reported, and only nine were tuberculous or even suspected of being so. In only fourteen children, including those who died, was tuberculosis found, or even suspected. This is a small number among 287 tuberculous mothers—only one in twenty.

In view of the widespread connection in the public mind between tuberculosis and pregnancy, it is interesting and significant of the intellectual honesty of these women that the majority did not claim any relationship between the two conditions. Only one third of those pregnant at any time found that the disease began or recurred with a pregnancy or after a delivery or an abortion. But, of all women pregnant before "cure," 44 per cent had found their tuberculosis adversely affected.

Of course, the large number who undoubtedly refrained from pregnancy deliberately must have believed it unsafe. Moreover, we know nothing about the women dead before reporting, nor how many refrained from marriage because of their tuberculosis.

The majority nursed their children, and nursed them for long periods.

Labors were reported to be difficult and instrumental in a large number of cases.

Of accidents in childbirth, the most notable were the postpartum hemorrhages that occurred in 44 instances, or 13 per cent—more than six times the usual frequency in the general population.

Menstrual histories showed half with disturbances, mostly dysmenorrhea.

No bad effects were noted after any of the eighty artificial abortions reported, though a few onsets and recurrences occurred after some of the 101 spontaneous abortions.

---

* From the Trudeau Sanatorium, Saranac Lake, N. Y., in cooperation with the National Committee on Maternal Health, 2 East One Hundred and Third Street, New York.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

* Owing to lack of space, this article has been abbreviated in The Journal by omission of the tables. The complete article appears in the Transactions of the Section and in the authors' reprints.

From another point of view, however, the study is satisfactory because the results seem reasonable and on the whole a justification of reason, good sense, and conscientious procreation. Thus the women were either sterile—and we must assume largely voluntarily so—or they had few pregnancies, and, after Trudeau at least, did not bring these to delivery unless the situation seemed to warrant it. There is nothing to indicate that this group of women were using tuberculosis as an excuse for not bearing children. On the contrary, they evidently wanted children very much and were willing to take extra risks to have them, and when they did have them took extremely good care of them, as well as of themselves.

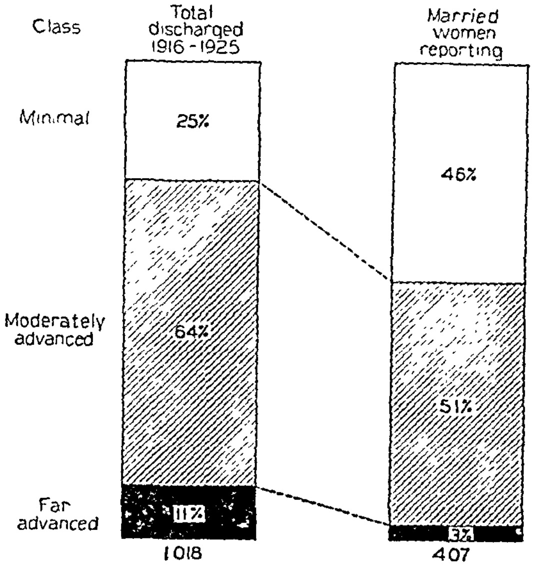

Chart 1.—Comparative classification of tuberculosis among 1,018 Trudeau women patients discharged in ten year period 1916-1925, and 407 discharged from 1896 to 1924 reporting on obstetric histories.

The whole story is a good one for Trudeau and a triumph of teaching how to live so as to conserve strength and health in the face of real handicaps.

COMPARISON WITH WHOLE NUMBER OF PATIENTS

Compared with the rank and file of Trudeau patients, the group studied are somewhat selected, since all answering had at least lived and were well enough to write letters and fill in schedules, and had never been *so seriously afflicted.*

Of 1,018 women discharged between 1915 and 1925, *273* were dead by 1930, or something more than one in four. Of all deaths, 220, or 81 per cent, were from tuberculosis, half having taken place by the end of three years and three fourths by the end of five years.

As half of the women studied had been out of Trudeau for more than *fifteen years*, it is obvious that they must represent the survivors of a considerably larger group, probably more *than a third again* as large. Whereas the whole number discharged between 1916 and 1925 had been out an average of *ten years* by 1930, some of the group studied had been out as long as thirty-five years, one fourth for more than twenty-two years, one half between fifteen and twenty-two years, and only one fourth for less than ten years, these averaging five years.

All had survived not only a condition of tuberculosis but also marriage: two thirds of them one or more pregnancies, and 59 per cent the bearing and rearing of one or more *children.*

Finally, not quite one woman in ten claimed to be worse off than when she left Trudeau.

CLASSIFICATION [1]

The women studied were in a less serious condition than the whole number discharged, with more classed as *minimal* and moderate, and far fewer as far advanced (chart 1).

Chart 1 shows the comparative classifications of the *two groups.*

The death rates for the various classes, 18 per cent of the minimal, *26* per cent of the moderately advanced, and 52 per cent of the far advanced, dead ten years later, indicates the kind of selection going on which resulted *in the final distribution* of our group.

Chart 2 and table 2 show the distribution into six classes *of the 484 women reporting. In the following* discussion the six classes are usually considered separately, and are referred to in ascending order of seriousness from class 1, the nontuberculous, to class 6, the far advanced:

Class 1, *nontuberculous:* The fifty women classed as nontuberculous were all discharged between 1915 and *1921, most of them from 1918 to 1920,* and it is just possible that these were drawn largely from the group of women with epidemic influenza. They had a relatively large number of abortions, both before and after "cure" at Trudeau, *and* their general condition was apparently rather poor, as shown by frequent entries of complications such as bronchitis, *hyperthyroidism or cardiac decompensation.* They have been kept in this study for purposes of comparison and as a *sort of check on the difference between the* reactions to treatment of definitely tuberculous patients and those otherwise affected.

Class 2, doubtful: This apparently meant that seven were probably not tuberculous, as compared with the next group.

Class 3, suspected: This includes the twenty who probably were tuberculous and resembled in their reports the moderately advanced group, while the doubtful ones were *more* like the *minimal.*

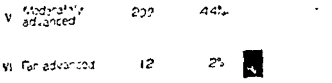

Chart 2.—Classification at Trudeau of 484 married *women graduates* studied.

Class 4, minimal: One hundred and eighty-six, or 39 per cent, exhibited the smallest degree of definite tuberculosis.

Class 5, moderately advanced: Two hundred and nine, or 43 per cent, were in the next most serious condition.

Class 6, far advanced: Only twelve, or 2 per cent, were in the worst condition. All had been married before contracting tuberculosis, and only two reported any pregnancies after being at Trudeau.

---

[1] The scheme of classification is that adopted by the National Tuberculosis Association, aside from the omission of three subgrades of each class.

CONDITION ON DISCHARGE

The condition on discharge is shown in table 2 by classes. The great majority were considered tuberculous but nonactive, 303, or 62 per cent, being either "quiescent" or "apparently arrested." The next largest group were still actively tuberculous, 22 per cent, being either "unimproved" or "improved."

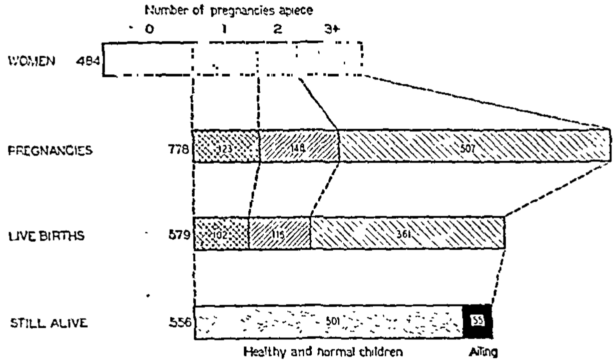

Chart 3.—Pregnancies and outcome: First bar represents whole group of 484 divided according to number of pregnancies reported; second bar shows total pregnancies; third, live births, the difference in length of each section indicating losses; last bar shows total children alive at time of report.

PREGNANCIES AND OUTCOME

The whole picture of pregnancies and outcome is shown in chart 3. The first bar indicates 484 women, divided into four parts according to the incidence of pregnancy. The first part is the 167 women who never were pregnant, while the rest of the bar is the 317 who were. These were made up of 123 who had only one pregnancy: next 74 who had only two, and the last is the 120 women who had three or more, averaging four pregnancies apiece.

The second bar shows the number of pregnancies, 778 in all. Their allotment is indicated by the lines connecting the two bars at the points marking the one, two and higher orders. This bar is made on the same base as the first, so that its length, a little over one and a half times the first, shows that pregnancies for the whole group averaged only 1.6.

As 40 per cent of the pregnant women had one or more losses by abortion, stillbirth or neonatal death, the number of living births is considerably lower, as shown by the third bar.

Among 778 pregnancies, 199 were lost before or at birth, leaving 579 living births and making a total ratio of 36 to every 100 living births. The losses were made up of 181 abortions, of which 80 were operative and 101 spontaneous; 8 stillbirths, nearly all of first pregnancies; and 10 neonatal deaths, nearly all in the first few hours and scattered through various orders. Details are shown in table 4. The losses increased with the number of pregnancies as follows:

Of 123 with one pregnancy, 39 per cent failed of a living birth, a ratio of 21 losses to 100 live births.

Of 74 women with two pregnancies, 23 per cent failed to carry all through, a ratio of 29 to 100 live births.

Of 120 women with three or more pregnancies, 38 per cent failed to carry all through, a ratio of 40 to 100 live births.

CARE OF SURVIVING CHILDREN

The last bar of chart 3 shows 556 children alive at the time of the report and represents a survival rate of 96 per hundred live births.

Of the remaining 556 children, 501 were reported to be "normal, healthy and robust," with only 55, or fewer than one in ten, other than entirely well. In only nine cases was tuberculosis found or suspected.

This good report is obviously due to the fact that the mothers applied the principles of hygiene they had learned from their own experience to their children. A further evidence is the large number who reported health examinations for their children, 60 per cent of all, and three fourths of those who believed their tuberculosis to have been adversely affected by pregnancy.

Another remarkable feature is the large number of women who nursed their babies. Among the 287 who bore living children, 203, or 71 per cent, reported nursing, although most of these live births were after "cure" at Trudeau and in spite of the general teaching against nursing by tuberculous women.

FERTILITY AND GENERAL CLASSIFICATIONS

The definitely tuberculous women had more pregnancies than the other two groups, the per capita number being 2.5 for classes 4 and 5, and 2.9 for class 6, as compared with 2.3 and 2.4 in the nontuberculous and doubtful classes.

The number of pregnancies reported by each class is shown in table 3. It will be seen that the majority of each class had no more than one or two apiece, except in the far advanced class, half of whom had three or more. The total incidence is shown in chart 4 by classes. Here it may be seen that the moderately advanced class had the largest proportion with no pregnancies.

Losses before and at birth increased with the seriousness of the disease, so that they were in a ratio of 29 to 100 living births in the minimal, 40 to 100 in the moderately advanced, and 54 to 100 in the far advanced.

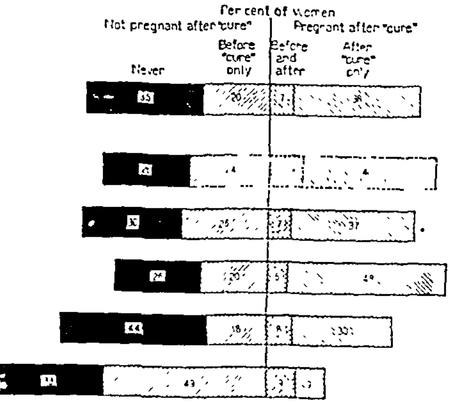

Chart 4.—Incidence of pregnancy before and after "cure" by classes: Vertical line is for "cure" at Trudeau; bars show percentage distribution; all to the left are those not pregnant after leaving sanatorium.

INTERRELATIONS OF TUBERCULOSIS AND PREGNANCY

Of the 484 women, 218 were married before and 266 after they had contracted tuberculosis, or at least before their condition was questioned. The two groups had about the same proportion who were never pregnant. Those marrying before had more pregnancies apiece and not nearly so many prenatal losses.

There are two determining factors in the distribution of pregnancies, survivals and losses: First, there is the effect noted by the women of their pregnancies on their tuberculosis or supposed tuberculosis. Women noting a positive effect numbered 103 and are grouped together as A, and all the rest, numbering 214, who were pregnant are grouped together as B. Group A, as compared with group B, had more pregnancies and more losses and more difficult labors, and did not make out quite so well with their children who lived.

Second, there was a distinct difference in the number of pregnancies, the losses and survivals according to whether these occured before or after "cure" at Trudeau.

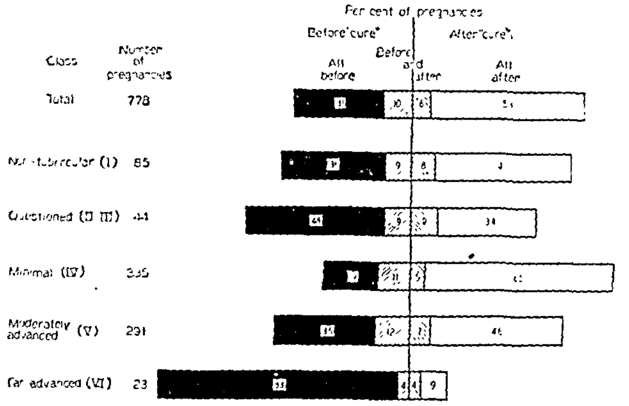

Chart 5.—Pregnancies before and after cure: same as chart 4, except that bars represent total pregnancies instead of women, and black portions represent pregnancies of those women who were *pregnant only before* "cure."

These two factors influence the whole tone of the reports far more than do such considerations as age or classification of disease. They are used, therefore, as the basis for comparison, all the women being divided into A and B groups and thereafter into the period for which they report pregnancies.

GROUP A

In all, 103 women, or about one in three, reported some connection between her tuberculous condition and pregnancy, either by way of onset of the disease during or immediately after pregnancy, abortion or delivery, or definite relapse, or a return or increase of symptoms, or appearance of the disease in one or more of the children.

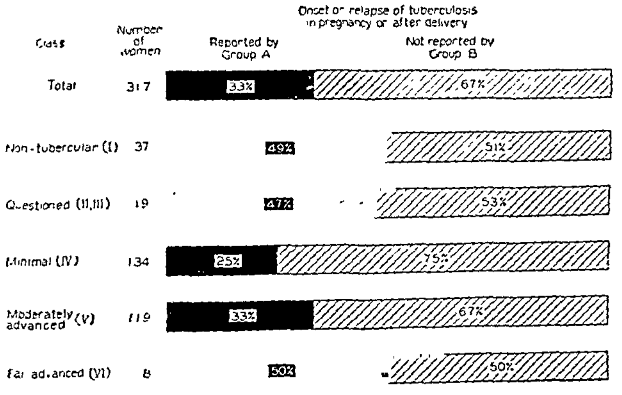

Chart 6.—Tuberculosis and pregnancy: Black sections show proportion in each class reporting adverse effect of pregnancy on their tuberculosis, called group A; all *others cross* hatched.

1. Onset of tuberculosis was claimed by forty women, thirty-eight who reported onset during pregnancy or within a few weeks or months after childbirth. Of these, thirty-five were first deliveries, three second or third, and twelve reported a relapse at subsequent pregnancies; and two who reported onset after spontaneous abortion, of whom one had a relapse later.

2. Relapse of tuberculosis severe enough to require special or prolonged care or even renewed "cure" was reported by thirty-three. Of these, twenty-nine were after childbirth and four after spontaneous abortion.

3. Recurrence of symptoms, such as fever, coughing or sputum, with an occasional hemorrhage, but of temporary character only, requiring no more than the ordinary care and rest at home, was reported by twenty-seven.

4. Finally, three women who noted no other effects reported having tuberculous children or children who were suspected cases in very early life.

The distribution of these women according to classification is shown in table 5 and graphically in figure 6. The proportion reporting a connection rose from a fourth in the minimal to a third in the moderately advanced, and to half in the far advanced class.

INCIDENCE OF PREGNANCY AS RELATED TO CURE

The incidence of pregnancy varied greatly before and after "cure," so that while only 20 per cent of the entire group had any children before coming to Trudeau, they had 41 per cent of all the pregnancies, or twice their quota, while the 80 per cent becoming pregnant after leaving Trudeau had only 59 per cent, or far less than their quota.

The reason for this is shown graphically in charts 4 and 5. Chart 4 gives the distribution of women in each class reporting no pregnancies at all, those who had them only "before" and those having them later. The 100 per cent bars are slid back and forward across a vertical dividing line which represents the "cure" at Trudeau. Of the 484 women shown in the first bar in chart 4, 167, or 35 per cent, were never pregnant, while 99, or 20 per cent, were pregnant only before "cure," thus leaving 218, or 45 per cent, who were *pregnant after* "cure," 33, or 7 per cent, being pregnant both before and after, and 185, or 38 per cent, only after.

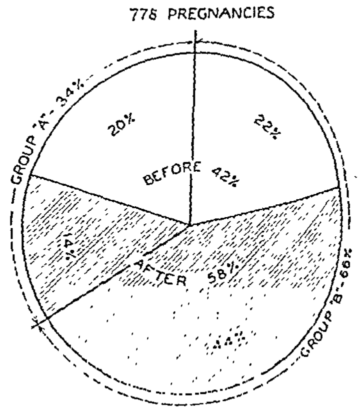

Chart 7.—Distribution of pregnancies reported by *group A and group B* according to occurrence before or after cure: white areas before, hatched after.

Chart 5 shows that 41 per cent of all the 778 pregnancies were before cure, being made up of 31 before only, and 10 per cent of those reported by women who were pregnant both before and after.

The lower bars in each chart show the distribution of pregnancies according to classes.

The relative incidence of pregnancy in groups A and B is shown in chart 7, which is a pie divided into four slices. The unshaded portions represent the 323 pregnancies that occurred before Trudeau. They were contributed in almost equal numbers by groups A and B, 20 per cent and 22 per cent, although the relative sizes of A and B would lead one to expect twice as many from B.

PER CAPITA PREGNANCIES BEFORE AND AFTER "CURE"

While a relatively large number of all pregnancies occurred before the patients came to Trudeau, an even larger proportion of children were brought to living birth.

The women who had pregnancies both before and after had a per capita total of 3.9 and lost one child apiece, keeping 2.9, and thus in spite of their high rate of losses, these had the highest effective fertility. This may be the mathematical basis for the reasoning advanced by those who urge a maximum birth rate, at whatever cost to mother or child, to keep numbers high.

The per capita pregnancies reported by groups A and B are in chart 10. The differences are even more marked, especially in the A group, in which those pregnant both before and after had four pregnancies in all and saved 2.6 in spite of losing 1.4. The B group, however, in spite of their lower number to begin with, saved the most, 3.2 out of 3.7.

The ratio of losses increased in the B group directly according to the number of pregnancies, going from 13 per hundred live births in the first order to 26 in the second and to 40 in all higher orders. This is not true of the A group, however, which lost 43 in the first order, 36 in the second and 41 in the higher orders.

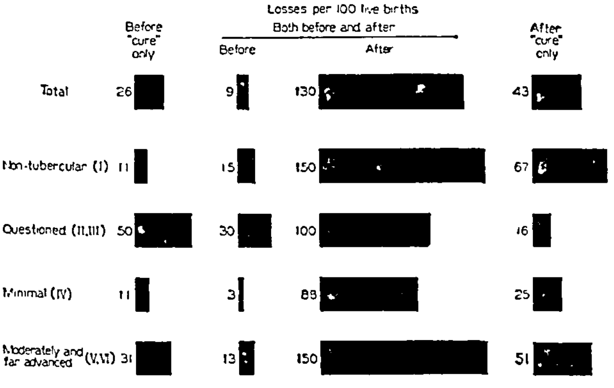

Chart 8.—Rate of loss before and after delivery: Bars show total abortions, stillbirths and neonatal deaths reported by women in each class per hundred live births at each period before and after "cure."

From this it would appear that the B group deliberately limited the number of their pregnancies and even more strictly their deliveries at term, resulting in a better general condition.

Charts 8, 9 and 10 show the rate of losses before and after "cure," first by classes of tuberculosis, then by groups A and B, and then by per capita pregnancies and losses reported at each period by groups A and B.

The losses were not evenly distributed, only 123 women reporting any abortions, stillbirths or neonatal deaths, and 194 carrying all pregnancies to term. Thirty women with 44 pregnancies failed to carry any through, thus leaving 287 who had any living children. Of the 30 who lost all, 22 were pregnant after cure. In group A, 9 of the 13 without any live births were among those pregnant only after "cure."

The rate of loss among those losing at all was extremely high; in group A 106 and group B 90 per hundred live births (table 7).

ABORTIONS

Because nine out of ten of all losses at any period were by abortion, and because interruption of pregnancy is so often advocated in the case of tuberculous women, it is interesting to see the character of these interruptions and how they varied by groups and by time of occurrence. The details are given in table 10. The significant items seem to be as follows: After cure, abortions were nearly three times as frequent as before, and the operative abortions four times as frequent. The group A women reported more spontaneous abortions before than after, these being related as about 6 to 4, thus indicating a relatively low vitality which did not allow carrying through to term. The group B women, on the other hand, reported over three times as many spontaneous abortions after "cure" as before, thus showing that tuberculosis had lowered their general resistance and carrying power even though their tuberculosis was not adversely affected by pregnancy. The operative abortions, however, were four times as frequent after as before in the two groups together but were relatively more frequent afterward among the B group, where they were five to one as compared to four to one in the A group.

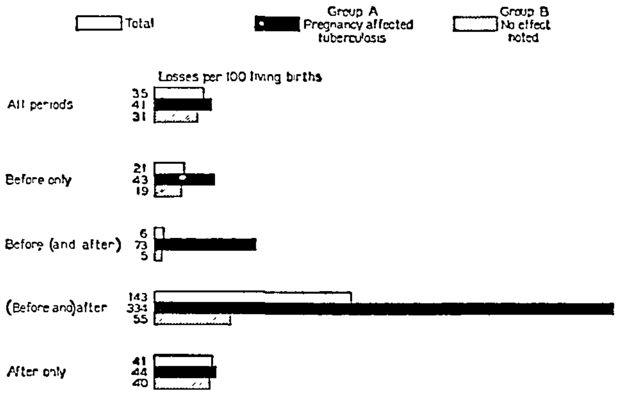

Chart 9.—Rate of loss before and after cure: same as chart 8, but by groups A and B instead of by classes.

No ill effects were reported following operative abortions.

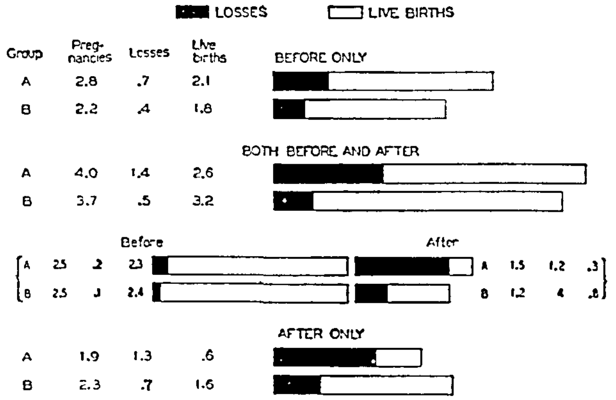

Chart 10.—Per capita pregnancies, losses and live births: Bars represent actual per capita losses and survivals at each period.

RELATIVE FERTILITY

The fertility of these women is apparently low compared with the general population. Little is known of the actual incidence of pregnancies and prenatal losses, only the exceptional abortion being recorded in the vital statistics or in hospital files. However, some figures are being gathered in birth control clinics here and abroad, where special inquiries are made of each applicant, not only as to her total living and dead children, but as to the total pregnancies, the outcome of each being recorded as exactly as possible. A study of the records of 13,005 women in fifteen birth control clinics [2] showed that even allowing for all errors of memory and deliberate suppressions, the rank and file of women have had nearly four pregnancies in ten years of married life and have three living children when they apply for contraceptive information. The ratio of prenatal losses reported is 19 to 100 live births. These Trudeau women have hardly more than half as many pregnancies during the marriages lasting fifteen years, and losses occur with them at about twice the rate.

MENSTRUAL DIFFICULTIES

Among 484 women, 228, or 47 per cent, reported menstrual difficulties of some sort; as pain, excess or scanty flow, or various combination of these. Dysmenorrhea led, 162 reporting it alone, and 22 with menorrhagia in addition. Menorrhagia alone was reported by 13. Scanty flow alone was reported by 15, and with dysmenorrhea by 14. Amenorrhea was reported by only 1 woman, and only 1 reported irregular menstruation. Thus, painful menstruation occurred in 200 instances, excessive flow in 35, and scanty flow in 30.

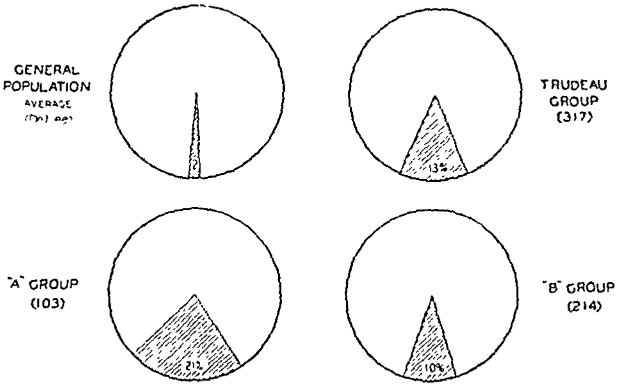

Chart 11.—Postpartum hemorrhage: Comparative distribution in general population and in Trudeau group.

There was some variation according to class. Thus, 41 per cent of the minimal class reported menstrual troubles and 50 per cent among the moderately advanced, while only 17 per cent of the far advanced so reported. Somewhat more of the A group had menstrual disorders.

Accurate figures on the normal incidence of menstrual disorders are not available, but it has been estimated that about one third of all women have real discomfort and one third of these are seriously affected. If, therefore, menstrual disorders are more frequent among the tuberculous, this point suggests one more means of preventive treatment.

CHARACTER AND DURATION OF FIRST LABOR

In all, 263 women reported duration of pain in their first labors, out of a total of 288 with deliveries at term of living children, and 237 as to the character of the labor, whether it was normal or hard and whether or not instruments were used.

Duration was from one hour to five days, with an average of sixteen hours, which is two less than the usual average for primiparas. This was perhaps due to the frequent use of instruments advised for tuberculous, cardiac and nephritic cases. But an unusually large number reported very short labors—a fourth less than six hours, half less than twelve, and three fourths less than twenty. The average of sixteen hours was thus made up by the fifty-one women who reported labors of twenty-four hours and over.

There was some difference in duration according to degree of tuberculosis, the minimal class averaging twenty hours, with one fourth over forty-three; the moderately advanced, sixteen with one fourth about thirty-six hours; and the far advanced fifteen, with the highest only twenty hours. This reveals a desirable tendency on the part of obstetricians to shorten the second stage of labor for disabled women.

Of the whole group reporting on character of labor, 40 per cent considered it "hard" and 60 per cent "easy." Instruments were reported used in 35 per cent of all, but in only 25 per cent of the "easy" and 92 per cent of the "hard" labors.

POSTPARTUM HEMORRHAGE

The most striking feature of these histories was the relatively large number of postpartum hemorrhages. A 2 per cent incidence is considered usual in the rank and file of deliveries, and in high grade maternity services it is far lower. Recently W. S. Smith [3] reported an incidence of 0.74 per cent in 9,000 deliveries at the Brooklyn Hospital over the period 1920 to 1930.

Of 317 women in this series, 44, or 13 per cent, reported postpartum hemorrhage at one or more deliveries. We have no way of measuring the seriousness of these hemorrhages, but it is a high incidence. Among the A group there were 22, or 21 per cent, not omitting the 13 who had no full-time deliveries. If these were omitted, the incidence would be 25 per cent. Among the B's, 22 also reported postpartum hemorrhage this being 10 per cent. The differences in incidence are shown in chart 11. Three fourths of the hemorrhages were in first labors, the total incidence being 11 per cent. Most of the labors were instrumental, and the average hours of labor twenty-seven as compared with sixteen for the whole group. The women reporting hemorrhages also reported a relatively high rate of menstrual disorders (especially menorrhagia) abortion and stillbirth, with a prenatal loss of one to each delivery. It would thus appear that these hemorrhages may reflect an atonic condition of the uterus in these women, though atony is no longer considered the prime cause of postpartum hemorrhage.

RECOMMENDATIONS

It will repay Trudeau or any sanatorium for tuberculosis to study the obstetric and gynecologic histories of its women patients, before and after they leave the sanatorium, because little is known of what constitutes the exact relation between tuberculosis and procreation. The mortality statistics tell only part of the story.

First, as to the mothers: Unless the woman dies immediately after delivery, she is entered as a death from tuberculosis or whatever the actual end was caused by, which may not have been tuberculosis at all; in any case, the record will not trace any connection with pregnancy.

Again, if she dies immediately after delivery, the complications of tuberculosis may not be entered, but she will be listed as a puerperal death, particularly if there is septicemia.

---

[2] Robinson, C. H.: Seventy Birth Control Clinics: A Survey and Analysis, Baltimore, Williams and Wilkins Company, 1930.

[3] Smith, W. S., Read before the New York State Medical Society in June, 1930.

But mortality statistics represent only end-results and show nothing of processes. The A and B groups saved the same number of living children apiece, but the A's did it at huge cost. When women die in childbirth, only the circumstances of that last delivery are recorded, with at most a bare statement as to the total parity. This does not take in any of the pregnancies terminating before viability, unless these have been operative interventions done in hospitals which report the exact facts. Hospital records usually list all early interruptions simply as dilation and curettage, and only the exceptional cases as therapeutic abortions.

The sanatorium, especially one following up its patients over long periods, practically for their lifetime, is in a position to measure not only end-results but also their significance in relation to the processes by which they were attained in each individual case.

Such a study might be made effective if a thousand women of child-bearing age should be taken in sequence after discharge and their histories followed, to find out:

1. Did they live, or die, and how long after entrance? If dead, the cause, age at death, and relation to tuberculosis.
2. Did they marry?
3. If not, why not? (Explain relation to tuberculosis.)
4. If they did marry:
    - (*a*) Were they ever pregnant:
        1. Voluntarily?
        2. Involuntarily?
    - (*b*) If not pregnant, was this voluntary or involuntary?
    - (*c*) If they were pregnant, determine:
        1. Interval and number of issue.
        2. Result of each pregnancy:
            - Abortion; when, how?
            - Stillbirth; why, when?
            - Live birth; condition at birth and character of labor.
            - Neonatal death; cause?
            - Later death, age; cause?
            - Present age and condition of living children.
    - (*d*) Effect on the mother's health from these experiences.

CONCLUSIONS

1. Pregnancy has a definitely deleterious effect on tuberculous women.

2. The more advanced the tuberculosis, the more deleterious the effect of pregnancy.

3. The women who took sufficient time before getting pregnant after being "cured" (three years or more), and who obey all rules and regulations after leaving Trudeau, fared better than those who did not.

4. Postpartum hemorrhage occurred in a very large proportion, amounting to 44 out of 317 cases, or 13 per cent.

5. Menstrual disorders were very common among this group of tuberculous women, being reported by 47 per cent.

6. Out of the 579 children born, 556 are alive, and 501 are healthy and well. Fifty-five are below par, and only 9 of these have had tuberculosis in any form, or have been suspected.

7. Education of the patient in the care of herself as regards tuberculosis as well as pregnancy is of the utmost importance.

8. Finally, the whole subject is a difficult one; experiences differ, there are many opinions. To pursue the right one, doing justice to the mother, to the child, and to the other members of the family, demands most careful thought, the exercise of the keenest judgment. Volumes have been written on this subject, but little has been done for the unfortunate gravida who has pulmonary tuberculosis. Sanatoriums, clinics, floating hospitals and rest homes have been provided for all ages and conditions of patients except pregnant women. Intelligent guidance through pregnancy, scientific supervision of the labor and puerperium, with proper care of the child and sanatorium treatment for the mother, should be the management for all such cases.

ABSTRACT OF DISCUSSION

Dr. Alexander M. Campbell, Grand Rapids, Mich.: This study is interesting because it refers to a selected group of very high class women. It shows that in spite of the fact that they are graduates of well known tuberculosis sanatoriums, they had difficulties in bringing children into the world. The mortality was high. Thirty per cent of these women reported that they were definitely made worse by the existence of pregnancy. The fetal loss was high. There were infections. There were all the things that would lead one to assume that, if an intelligent class of women had been trained to take care of themselves as they had, their pregnancies were fraught with so many dangers that the ordinary tuberculous woman must be made to realize the danger of going through pregnancy with this terrible condition. Many of them aborted spontaneously; many aborted operatively; many suffered from menorrhea. There was everything to indicate that all was not well when these women underwent the dangers of pregnancy. The cheerful side of the picture, however, is that nearly all the children were healthy, and that, of course, gives some argument for the adherence to the principle of letting these pregnancies go on uninterruptedly. It seems to me that the lesson to be learned from this study is quite obvious: that, by and large, pregnancy does not improve tuberculosis; that the tuberculous woman should avoid marriage: that if she becomes married she should be instructed as to contraceptive measures and that, if she does become pregnant and her tuberculosis is active and she is the asthenic type to which the authors refer, the pregnancy should be terminated if the patient consults the obstetrician in the early months of pregnancy. Frequently in my own practice, in the woman of advanced years, I terminate the pregnancy by abdominal hysterotomy, and I sterilize the woman at the same time. I think this brings out another point seen in general work, and that is that the great national malady in this country is fatigue. It is seen in every decade of life. The panacea is rest. Women of the asthenic type who become pregnant must be given a great deal of rest, whether they are tuberculous or not.

Dr. C. S. Bacon, Chicago: The same points that were emphasized a few moments ago in regard to the sociological factors in heart disease apply here. A patient who is able to get good care during pregnancy, including proper rest and proper diet, may go through a pregnancy without danger. The question of what to do for the poorer class of patients has been touched on by Dr. Campbell, and the importance of sanatorium care, or proper care in some way during the pregnancy, has been emphasized. Since the establishment of the Municipal Tuberculosis Sanitarium in Chicago, we have had sufficient accommodation for all women who were unable to receive care at their homes. It was thought when that institution was first started that a large number of patients—we estimated at the time probably 200 or 300 a year—would take advantage of those facilities. As a matter of fact, only a few each year have been taken care of in the institution. The difficulty is not that there is no place for them, but most of the patients that should come to the institution are not able to leave their families, many of them being women already with families. Those that have come have had their children and have had fair care, and the report, while not in any way as gratifying as that shown at Trudeau, has been of some value. However, we find this: Most of the specialists in tuberculosis who are not obstetricians insist on terminating the pregnancy at the earliest possible moment without much regard to the prospect of the future or the result of the pregnancy. I think that obstetricians generally are rather urged by their colleagues to terminate pregnancy more frequently than they themselves think is necessary. A number of eminent specialists refuse to terminate pregnancy in the tuberculous woman, holding that the tuberculous condition is not made worse by the carrying through of the normal pregnancy and labor—that it is not worse than if an abortion is induced. I believe that these factors show that we should be more conservative in the termination of the pregnancies. Except in a few cases, in which the women cannot have the proper care at home, there is not very much use in intervening.

DR. HYMAN J. EPSTEIN, New York: The speaker emphasized what has been heard before: "Don't let the tuberculous woman get married, don't let the married tuberculous woman become pregnant, and don't let the pregnant tuberculous woman give birth." But this perhaps is a pessimistic attitude. The woman who wants to have a baby will not listen to such pessimistic advice. The fact is that these women are willing to take any chance that offers them the possibility of offspring. After the war I saw many patients come to the doctor for a termination of pregnancy in the early weeks—the fifth, sixth or eighth week—and all the doctor wanted was a certificate from her physician stating that she had what they call in Germany *lungenspitzencatarrh*, or tuberculosis. A touch of tuberculosis was sufficient for them. That was all they wanted. But the women also are entitled to live their lives, and I believe that if a woman has a chance to have a baby, even with the risk of a stillbirth (although more than 500 women in this study had live children) she is entitled to consideration.

DUST AND PULMONARY DISEASE *

ALBERT E. RUSSELL, M.D.
Passed Assistant Surgeon, United States Public Health Service
WASHINGTON, D. C.

The subject of dusty trades has received much consideration in recent years. The advances which have been made in all branches of industrial medicine have helped to center attention on dust and its effect on the health, as the number of the workers in dusty trades is larger than that of any other group that is exposed to a single industrial hazard; and an additional reason for increased interest in this subject is that the study of mortality statistics has revealed the fact that workers in dusty trades have an excessive death rate from tuberculosis as well as from other respiratory diseases.

The Public Health Service has recently completed a series of studies of the effects of the principal varieties of dust encountered in industry. These studies cover the following phases of the subject:

1. The cement industry, representing calcium dust.
2. Silver polishing, representing metal dust.
3. The granite industry, representing silica dust.
4. The coal industry, representing carbon dust.
5. The cotton industry, representing vegetable dust.
6. Street sweeping, representing municipal dust.

While these dusts contained principally the elements indicated, they were all mixed dusts. There are very few dusty trades in which the workers are exposed to a specific dust only, as that of silica, carbon or calcium, without the presence of other elements in the dust. The cement dust that was analyzed in these studies contained about 60 per cent of lime and 1 per cent of silica, the granite dust about 35 per cent of free (crystalline) silica and 2.07 per cent of lime. The coal dusts, also, were mixed with rock dust, and in many instances in sufficient quantities to influence the character of the pneumonoconiosis. It may be possible that some of the other elements in these dusts exert a synergistic or inhibitory action; for instance, the lime in cement dust might prevent the development of active tuberculosis. The rôle of dust as a vector of bacteria has been mentioned frequently and there is no doubt in some cases that it figures prominently in the production of excessive morbidity and mortality from respiratory diseases. The harmful action of dust on the tissues and the reaction incident to its removal lower the local resistance and thus favor bacterial invasion.

In the intelligent consideration of dust as an etiologic factor in pulmonary disease, the following points must be taken up:

1. The chemistry of dust.
2. Its concentration.
3. Petrography; the size of its particles.
4. The length of exposure to it.
5. The effects produced:
    - (*a*) morbidity;
    - (*b*) physical condition;
    - (*c*) mortality.

THE CHEMISTRY OF DUST

The dusts most frequently encountered in the industries are inorganic, and, incidentally, these are the most harmful. It has been shown that silica alone produces more permanent pulmonary damage than all other elements found in industrial dust. Originally the dangerous properties of dust were supposed to be dependent on certain physical characteristics, such as hardness of particles and sharpness and angularity of edges. No doubt the physical or mechanical action of dust is a factor in producing chronic pathologic conditions in the upper respiratory passages and the bronchi, but the theory that silicosis is produced solely in this manner by such action has been generally abandoned.

Dr. Collis, in his statement relative to the chemistry of dust,[1] was one of the first to draw attention to the chemical, rather than the physical action of dust. He said: "Generally speaking, dusts are more injurious as their chemical composition differs from that of the human body or from the elements of which the body is normally composed, whence it follows that animal dusts are less injurious than others."

In 1922 Gye and Kettle[2] asked the question, "Why is silica conspicuous, and possibly, alone so, among the common dusts capable of producing extensive fibrosis?" They found that, in experimenting with mice, which possess a high degree of immunity to tuberculosis, if silica was introduced into these animals along with tubercle bacilli, the tissues underwent a considerable degree of necrosis, which fact, after a preliminary lag of a few days, made it possible for the bacilli to proliferate abundantly in the coagulum, being protected by the latter against the cellular defense of the body. These results provided a partial answer to their question, in that the poison did not remain in a particular form at the site of inoculation for any considerable time but was either fixed locally or gradually removed by the phagocytes through the body fluids; when present, it behaved as an active cell poison; but, with its gradual disappearance, normal processes of repair became evident. In a more recent article, Kettle[3] gives further explanation as to why tubercle bacilli proliferate in the necrotic center of the silica lesion, naming the following reasons: "First, the mere mechanical protection of bacilli during their early lodgment in the body; second, the rich pabulum furnished to the disintegrated cells; or third, the stimulating action of silica on the growth of the bacilli." It is also well known that tubercle bacilli grow well in a medium rich in colloidal silica.

2. Gye, W. E., and Kettle, E. H.: Silicosis and Miner's Phthisis, Brit. J. Exper. Path. 3: 241-251, 1922.
3. Kettle, E. H.: Experimental Silicosis, J. Indust. Hyg. 8: 491-495, 1926.

Kettle's final opinion as to why silica dust is dangerous, as far as the production of tuberculosis is concerned, seems to be that it is not because of the fibrosis produced by the silica nor because of the damage which silica does to the lymphatic system, but that it is simply because of the presence of silica in the lung.

Gardner's experimental work with animals inoculated with a strain of tubercle bacilli of a low virulence and later exposed to dust is noteworthy.[4] A series of guinea-pigs were primarily infected by the inhalation of tubercle bacilli of low virulence. The animals developed an infection, which finally healed by resolution. By placing groups of these infected animals in dusting chambers and subjecting them to at least two months' exposure to dusts, a reactivation of the primary tubercles was brought about as late as from 206 to 400 days after infection. Of these pigs exposed to quartz dust, 73.6 per cent exhibited evidence of a progressive tuberculosis, and likewise 31.8 per cent of those exposed to carborundum dust (SiC) and 26.3 per cent of those exposed to granite dust. The groups of pigs exposed to marble and coal (bituminous) dusts did not undergo a reactivation of the disease. Dr. Gardner states that "the reaction appears to be a specific result of the inhalation of certain definite types of dust, for evidence has been produced to show that factors like overcrowding, lack of proper ventilation and light, endemic pneumonia, and nonspecific inflammations have not influenced this type of tuberculous infection." Apparently the same effect is not obtained with other bacteria in the dusted pulmonary tissues as with tubercle bacilli. The excessive amount of other respiratory diseases can be accounted for, however, by the lowered local resistance caused by the presence of the dust, the irritation produced by mechanical injury, and the diminution of the local blood supply by fibrosis.

CONCENTRATION OF DUST AND SIZE OF PARTICLES

It is necessary to know the concentration of a dust before a definite decision can be made that such dust is harmless per se or that its lack of harmful effect is due to some other element existing in combination with it. A low concentration of a dust containing a high percentage of free silica (quartz) may produce as much harm as a higher concentration with a lower percentage of silica. The fallacy of estimating the extent of dustiness without dust counts is obvious, in consideration of the fact that the particles found in the lungs of workers are less than 10 microns in diameter and therefore cannot be seen with the unaided eye.

Studies of groups of workers exposed to varying concentration led to the conclusion that 10 million particles per cubic foot of a dust containing about 35 per cent of free silica, as quartz, could be tolerated without great injury. Workers exposed to this concentration over long periods developed a mild fibrosis, not of sufficient severity to predispose them to tuberculosis.

The concentration of dust is, hence, a deciding factor in determining dust hazards. If the effects of dust can be shown by roentgen or by physical examination, proof of excessive dust is given; however, if a worker is exposed to an unknown quantity of a supposedly dangerous variety of dust and does not develop pulmonary changes, it is possible that the concentration is within tolerable limits.

PETROGRAPHY

The petrography of dust is valuable in deciding its effects; for instance, the chemical analysis of cement dust indicates that there is a total of 15.2 per cent of silica present, while the petrographic analysis shows that it contains only 1 per cent of free silica or quartz, the known dangerous element. Likewise, chemical analysis of granite shows that approximately a total of 70 per cent of silica is present in it, while by petrographic analysis only 35 per cent of quartz is found.

LENGTH OF EXPOSURE TO DUST

The length of exposure to dust is evidently a great factor in the production of disability. Observations based on physical examination show conclusively that the frequency of the occurrence of silicosis is in direct relation to the amount of dust and the length of service.

The effects produced by the inhalation of dust are now considered under the headings of morbidity, physical condition and mortality. Silicosis and tuberculosis are outstanding here, as they cause a greater amount of disability and mortality in the dusty trades than any other diseases or combinations of diseases.

EFFECTS PRODUCED

Morbidity.—The observations made on granite workers showed that, when a patient who had a latent tuberculous lesion began work in the granite industry, he developed silicosis more rapidly than workers who had no signs of tuberculosis nor history of prolonged exposure to it. It should be determined whether or not a worker has any signs of latent tuberculosis or a history of exposure before he is allowed to enter a dusty occupation.

Most of the illness among the groups of workers studied is due to respiratory disease. The groups exposed to greater amounts of dust have the higher rates. Approximately half of the respiratory diseases were diagnosed as influenza, or grip.

The coal miners (anthracite) had more bronchitis than any of the other workers. The rate was much higher and approximated half of the incidence of influenza, or grip, among them. The rate for granite workers was quite low, considering their exposure to dust.

There is an excessive amount of tuberculosis among granite workers, its incidence being greater than that of influenza. The lower incidence of tuberculosis among gold miners, who are exposed to a high siliceous dust, may be due to the shorter length of their service compared with that of granite workers.

The iron and steel workers, who have had the lowest incidence of diseases shown in these figures, have the highest rate of sickness from pneumonia. The anthracite miners were lowest in pneumonia.

The records from which data were taken for the general manufacturing group were provided by plants in the Northern states and east of the Mississippi River. Practically all the groups have similar climates, and it is believed that these rates are comparable and that variations in climates have not materially affected them.

Physical Condition.—A discussion on the points considered in making a diagnosis of silicosis may be found in United States Public Health Service Bulletin 187.

---

[4] Gardner, L. U.: Am. Rev. Tuber. **20**: 833 (Dec.) 1929

Roentgenography gives more information by far than any one other method used in diagnosis; this fact does not, however, warrant the nonemployment of other methods. Early silicosis is not easily demonstrated by roentgenography, because the fibrosis is new and does not produce as dense shadows as it does later from contraction and proliferation, which characteristics are incident to long duration. The presence of the fibrosis of early silicosis can be detected by physical examination. Also, there are in the disease stages in which it is not possible to diagnose or to exclude the presence of tuberculosis without the aid of physical examinations, especially in an early tuberculous complication. That there is a tendency to rely solely on the x-rays as a means of diagnosis is the reason why early tuberculosis in silicotic patients is so often overlooked. I have found that the râles of tuberculosis in these cases are latent or post-tussic, just as in uncomplicated cases.

Tuberculosis was frequently found in our cases with the early lesions in the bases of the lung, and the characteristic râles could be heard in this location. Routine analysis of sputum cannot be too strongly urged. Too often the cases are considered to be free from bacilli when only one or two specimens have been examined. Series of ten are of more value.

A group of cases was selected from workers in several dusty trades. It was found that the character of the fibrosis is similar in a number of these cases, but this similarity does not by any means express the same amount of disability. The fibrosis of the cement worker has a similarity to that of early silicosis of granite workers, but it has been shown that the condition does not progress in the same manner and that the cement workers do not develop tuberculosis at any higher rate than the general population.

It was an interesting observation in the study of workers in dusty trades that, when patients had been exposed long enough to develop silicosis and then changed to nondusty occupations, they did not thus materially lessen their chances of escaping a final tuberculous complication. Granite manufacturers were found to have almost as much tuberculosis as stone cutters and lumpers; many of these manufacturers were formerly stone cutters and no doubt developed silicosis before establishing themselves in their new occupation.

One patient, who developed tuberculosis at age 50, had spent twenty years on a farm, after having worked fourteen years in the granite industry. Other investigators[5] have found that silicosis apparently continues to progress and that respiratory diseases are still frequent complications even after cessation of exposure to dust.

Mortality.—The influence of dust on mortality from tuberculosis is clearly indicated in the following figures. New methods of manufacturing stone which created excessive dust by the use of pneumatic tools were introduced in the granite industry about the beginning of the present century, and the tuberculosis rate has increased rapidly with their use. The rate has risen in direct proportion to the length of time during which they have been employed, as follows: 1.5 per thousand, 1890-1894; 10.8 per thousand, 1910-1914; 19.5 per thousand, 1924-1926 (the period of our observations).

A consideration of the mortality statistics of Barre, Vt., shows that there has been an excessive death rate from pneumonia and other respiratory diseases (tuberculosis excluded) during this period.

There is great contrast between the age of mortality of workers using hand-pneumatic tools, and that among males in rural Vermont, although the rate of the latter may have been influenced by the fact that many disabled cutters move to rural districts.

SUMMARY

Morbidity and mortality records indicate that workers exposed to dust have excessive rates of respiratory diseases.

Inorganic dusts produce more pulmonary disability than organic dusts.

Silica (SiO_2) of the crystalline variety (quartz) is the element in dust which produces greatest pulmonary damage, and it is present in varying extents in most industrial dusts.

Silicosis is insidious in its onset and progress and presents but few symptoms or physical signs in its early stages.

Silicosis is almost invariably complicated by tuberculosis after a number of years of exposure, the time depending on the concentration of the dust and the percentage of free silica which it contains. Latent tuberculosis in persons entering dusty trades is usually activated after shorter exposure to siliceous dust and has more characteristics of the disease.

Before a dusty trade can be absolved of its danger or stamped as dangerous, the concentration of dust and its chemical and petrographic analysis must be shown.

Masks frequently give a false sense of protection. Removal of dust at its source is preferable.

There has been a great reduction in the death rate from tuberculosis among the general population during recent years, while among workers in dusty trades there has been a great increase during the same time in the death rate from this cause.

ABSTRACT OF DISCUSSION

Dr. C. R. Orr, Buffalo: Regarding the nature of the dust offending, it is conceded that sand is the greatest offender. But it has been my experience that any dust can create disturbance in the lungs, which will be manifest by clinical signs and which will in time incapacitate the individual for his daily vocation, some sooner than others. I have records of one position in which death followed exposure after eighteen months for one individual and thirty-two months for another, his predecessor. Both entered their occupations with supposedly sound lungs and passed through the three stages of fibrosis that Dr. Russell has so ably shown us. The diagnosis of these cases is almost entirely by roentgen ray; occasionally I fall by the wayside, but after diagnosis is made a complete history of exposure is taken. On the other hand, there is in the exhibit an excellent example of the danger of depending entirely on the roentgen ray for diagnosis. The film is almost a typical advanced second stage occupational fibrosis, but in reality it is a generalized metastatic malignant growth. I have in mind one particular case in which the diagnosis of second stage fibrosis was made. The history gave the patient's occupation as an actor with no apparent dust hazard. Repeated inquiries brought no light until, finally, I inquired into the particular form of acting of the individual and learned that he was a "buck and wing" dancer and for twenty-five years had scattered sand on the stage before dancing. Dr. Russell spoke about the complications of tuberculosis, bronchitis and similar conditions that attend dust irritation in the lungs. It has been our practice in the hospital whenever possible to follow the cases to the autopsy table. I have found that although records show that there are about 95 per cent of these cases of silicosis which show a tuberculous infection superimposed on the silicosis, that percentage is rather high. On the other hand, I am finding tuberculosis a complication in many cases of anthracosis. Dr. Russell made a statement in one of his previous talks to the effect that he was finding tuberculosis in the bases in his study of anthracosis. I should like to ask him what he thinks now in regard to that infection.

Hyg. **6**: 199 (Sept.) 1924. Tattersal, Norman: The Occurrence and Clinical Manifestations of Silicosis Among Hard-Ground Workers in Coal Mines, ibid. **8**: 466 (Nov.) 1926.

Dr. Edward J. Rogers, Pittsford, Vt.: My experience in this problem is almost entirely clinical. We get cases with such a history as the following: A man has been cutting granite for a number of years and has often had to lie off during one of the strikes or during one of the adjustments for labor trouble. When he returns to work he finds that he is not as strong as he was when he quit work. He is apt to be bothered with shortness of breath, indigestion and lack of strength. Incidentally he spits a little blood or has pleurisy pains. He goes to his family physician, who tells him that he has a little pleurisy or bronchitis. He then goes to another physician and is told the same thing. Then he tries a physician in Montpelier or at Burlington. Each physician sends his sputum away for examination and after a time the specimens are positive. Finally the patient enters a sanatorium and within six to eighteen months he dies. One patient was under sanatorium treatment as long as seven years before he died, but at no time was he able to return to work. The medical men working in Barre feel that little can be done for these men after the acid-fast bacillus is found, and the general policy is to encourage the granite cutters to keep at work as long as possible, because they earn high wages and while they are earning them they do not appeal to the town or city for support. They provide more fully for their own families and they are out of the house for at least eight hours a day. The physicians who tell them that they have a little pleurisy or a little bronchitis and keep them at work are probably handling the cases correctly. Economically it is better to keep them at work, and they probably live just as long. The physical signs are not those of an ordinary case of clinical pulmonary tuberculosis. The first time they come into an office the physician is able to pick up a seemingly dry pleurisy at one base. They do not have râles in the upper half of the lung, but three or four months later they are apt to have a definite area of dulness, bronchial breathing and sometimes amphoric breathing. After entering the sanatorium they usually live from six to eighteen months.

Dr. Albert S. Gray, Hartford, Conn.: I understood Dr. Russell to say that it was somewhat difficult to diagnose these cases by the roentgenogram in the early stages; that they were more readily diagnosed by physical signs and symptoms. I should like to know what these physical signs and symptoms are. And I should like to know, too, about the number of years it takes for the development of silicosis in the workers exposed to various concentrations of dust; also whether one of these workers who develops a first stage silicosis will continue to develop fibrosis of the lungs if he changes his occupation for a different one.

Dr. R. T. Legge, Berkeley, Calif.: Recently it was my privilege to make a survey in a new field in which silicosis is the result of a dusty occupation. In the southern part of California along the Coast Range Mountains, there are large deposits of diatomaceous earth. This earth consists of fossilized microscopic plants from the sea whose silicious remains during the Miocene period formed the deposits. This material is now mined for the manufacture of fire-bricks and for filtering purposes. On account of many cases of tuberculosis in this part of California, the dust from the mills aroused suspicion, which led to an investigation. The equipment consisted of an especially made automobile which had a portable x-ray machine and also a dark room. One hundred and eighteen employees were selected and chest plates were taken. Each man was given a thorough physical examination. It is rather interesting to note that, in spite of the large amount of silicon present in this dust, only about 1.5 to 2 per cent had active tuberculosis. The x-ray plates, however, showed in every case evidence of an early silicosis or fibrosis. During the physical examination of the chest, râles were unusual and, when present, were usually in the base and not in the apex, as is usual in the case of tuberculosis. There were also many cases of clubbing of the fingers, which is rather characteristic in this type of pneumonoconiosis. In making chest examinations, little change was found in expansion. This is in contrast to cases of quartz silicosis which I have noted among California miners, in which a definite decrease takes place early. Quartz silicosis may be detected by roentgen methods as early as within a year's time. There are three stages: the first may be a normal expansion of 3 inches or more; the second, 1 or 2 inches; and the third, none at all. In the latter stage a deep contraction, particularly in the base of the right lobe of the lung, is uncommon. Death is usually due to a superimposed tuberculosis. Every mine, quarry or other dusty trade should insist on a complete physical and roentgen examination of the chest at the time of employment and at periodical intervals. The roentgenographic method is the best for detecting early stages of silicosis.

Dr. A. E. Russell, Washington, D. C.: I think that Dr. Orr misunderstood my statement in regard to the basal tuberculous lesions in coal miners. Some miners exposed to a large amount of silica dust in rock drilling show the basal type of tuberculosis with more silicosis than anthracosis; but the majority of miners are exposed to coal rather than rock dust. A statement was made in the bulletin reporting the granite-cutting investigation that rest and sanatorium treatment did not help the workers much when tuberculosis had once become manifest. That is borne out by my study. The physical signs of early silicosis are reviewed in the bulletin, and I will not take the time to discuss them in detail. The principle points are a beginning impairment in resonance and a diminished tactile and vocal fremitus, with diminished breath sounds. Later, there is a diminished chest expansion. These points, together with roentgenograms, are the principal things on which I made my diagnosis. In regard to the workers in the diatomaceous earth in southern California, I have stressed the fact in my writings on silicosis that silica of the crystalline variety is, so far as is known, the most dangerous type. There are ten forms in which free silica appears, and I am always careful to designate free crystalline silica, or quartz.

DISABLING BACK PAIN

DIFFERENTIAL DIAGNOSIS AND TREATMENT *

ROBERT McE. SCHAUFFLER, M.D.
KANSAS CITY, MO.

My daily and sometimes hourly puzzle is whether a certain complaint is of mechanical or toxic origin. Is this particular back or knee or foot trouble caused by some congenital deformity or some traumatic injury or by some postural strain or is it some sort of an arthritis, or myositis or neuritis caused by poisons absorbed from some focus of infection elsewhere in the body?

In considering disabling back pain there are other possibilities which must first be cleared up. One must be sure there is no gross lesion, such as a compression fracture of a vertebra or a fracture of the transverse or spinous processes. Good roentgenograms, both anteroposterior and lateral, will settle that. One must also be sure that there is not some destructive bone disease, such as tuberculosis or cancer. Here again, the roentgenogram usually gives definite information. When there is doubt as to the interpretation, the spine should be immobilized and new films made after a two months interval. These usually settle the matter.

Again there is the question of reflected or reflex pain. There may be nothing the matter with the bones, joints or muscles of the back but root pain from locomotor ataxia or tumor or some other lesion of the cord. More often it is a simple reflex pain due to disease or displacement of some viscus. Finally, malingering or a psychoneurosis must be excluded.

Any case presenting a disabling back pain is entitled to a complete investigation. The history must be carefully taken. The physician must ask the patient about the onset of the pain, whether preceded by any accident, whether he has done anything unusual in work or play; also whether he has had any sickness in the month preceding the onset; any cold, sore throat, bilious attack or anything out of the ordinary. It is important to discover whether the patient had ever had neuritis or arthritis in the limb joints and whether any local focus was discovered or suspected. Special inquiry should be made as to the bowel function.

---

* Read before the Section on Orthopedic Surgery at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

A general history should be recorded and recent gain or loss of weight noted. There may have been a fall or a blow on the back. More often there is the history of a lifting strain. It is important to know whether the disability was immediate or after a few hours or days. If there was immediate disability or if the patient worked on through that work period but was unable to start the next period, it sounds like a mechanical lesion. If several days intervened before disability, it suggests a toxic lesion started up at the site of a mild trauma. A patient may have a mechanical lesion without any knowledge of the minute or hour when it began. These are usually postural, from habit or occupation, or perhaps from some unusual posture, such as long riding in a motor with an uneven seat or a back to which the patient is not accustomed.

The patient is observed as he walks into the office and as he sits down and stands up. Much can be learned from the way he handles himself. History should be taken quietly and the pulse, blood pressure, pupil reactions and knee jerks tested before the clothing is removed. The back must then be fully exposed. My set-up is an old fashioned piano stool, on which the patient sits and can be turned in any direction, and a pair of gymnasium rings hanging from the ceiling to which the patient can hold while standing to steady himself and by which he can stretch his back or chin himself.

The type of build is noted, whether long and slender and disposed to visceroptosis or short and thick set. I observe the back with the patient sitting and standing. Any lateral deviation, high hip or side shunt or curve is noted. Many women have old, slight, lateral curves which have existed since girlhood and are not the cause of symptoms. The anteroposterior curves, the amount of lumbar lordosis, any abnormal kyphosis and any asymmetry are noted. Any muscle spasm of the long spinal muscles should be noticed especially, and if none is noted, it should be seen whether movements or pressure produce muscle spasm. Then the range of motion permitted in flexion, side bending and rotation is tested. If this is limited the physician should try to decide whether it is due to partial ankylosis or to pain or fear of pain. Any points or areas of tenderness in the back to light touch or heavy pressure should be carefully noted. Careful distinction should be made between a site of pain and local tenderness. Once the patient's attention is called to it he will often show just where he has a pain at that time or frequently does have one, yet he says that pressing on the spot does not make it worse. In some reflex pains, a light touch hurts but firm pressure does not.

It is easy to pass the hands forward and note the chest expansion and the abdomen, whether thin or fat, normally firm or flabby, or whether pendulous; also, whether there is tenderness or muscle splinting.

The patient hangs from the rings and I note whether any abnormal curves of the spine straighten out or persist. Unless the patient is in much pain, recent lesions straighten out while old ones with structural changes do not. It is important to see how much the patient can overcome his deformity by his own efforts with the aid of a hand pull on a ring and perhaps a book under one foot. It is also important to see in what position he is most comfortable. One must have this information to know in what position to immobilize the spine.

Next the patient is placed flat on the back on the examining table, and the indirect tests are carried out; the thighs are flexed with the knees flexed and then with the knees straight and especial note is made regarding sacro-iliac pain and secondary sciatica. The abdominal examination is made at this time and, if there has been a midsacral pain suggestive of pelvic reflex, the physician may decide to make a vaginal or rectal examination.

The patient now usually goes to the x-ray room for films of the pelvis, lumbar and lower dorsal spine, both anteroposterior and lateral, and films of the upper part of the spine if there is a deformity or pain there.

The case in which the roentgenogram shows some abnormality may first be considered. There may be a tilting of the pelvis and lateral deviation of the spine. This may be due to an old faulty posture or to distortion due to pain. If it is the latter, muscle spasm should have been noted. Such asymmetry of the spine alone is seldom the cause of the pain for which the patient is seeking relief.

The roentgenogram may reveal a fracture or some destructive bone lesion. In that case the diagnosis is usually made or there is left only the problem of the cause of the erosive bone lesion.

There may be an increase of the lumbosacral angle which might be the cause of chronic strain and pain. There are occasional cases of true spondylolisthesis. This term is usually limited to a definite displacement between the fifth lumbar vertebra and the sacrum or a displacement between the fourth and fifth lumbar vertebrae. To justify the diagnosis, the displacement must be apparent in the lateral roentgenogram, which should be centered lower down than in the usual lateral view.

The roentgenogram may show congenital malformations of the spine. It may be puzzling to know whether these are the cause of the back pain that brings the patient to the physician. Misshapen vertebrae usually lead to deformity early in life and it is found that the patient has had an abnormal curve of the spine for years. Spina bifida occulta is seldom a cause of back pain. The more pronounced cases may cause bladder symptoms or may cause a weakness of the lumbosacral region which favors spondylolisthesis. Complete sacralization of the fifth lumbar vertebra rarely causes symptoms. If it does, they will be referable to strain between the fourth and the fifth lumbar vertebrae. Unilateral sacralization of the fifth lumbar vertebra is more likely to cause pain because of the unbalance of the spine. Impaction of transverse processes of the fifth lumbar vertebra is seldom a cause of pain. It would be better to say that true impaction seldom occurs without sacralization. If two or three plates are taken with the patient lying on the back and the tube is shifted up and down, one will show no impaction. If there is impaction there is usually some evidence in the roentgenogram of the formation of a facet. Spontaneous cure is often affected by arthritis and ankylosis; that is, secondary sacralization.

In general it may be said of the congenital deformities of the lower spine in adults discovered by the roentgen ray that they are seldom the cause of the pain for which the patient is seeking relief. If they have any effect it is as a predisposing cause; that is, the back may be a little weaker in the bony structure and so more subject to sprain or strain or to a low grade arthritis.

In middle aged or old people the roentgenogram often shows hypertrophic arthritis. There are the usual rims or spurs with bridging in the more advanced cases. One now has quite a problem to decide whether these changes are the cause of pain. It is known that quite often when roentgenograms are taken of older people for some other reason, these hypertrophic changes are noted in the spines of individuals who make no complaint of backache. When there is bridging at a few points which are irregularly placed, so that the check to motion is not symmetrical, it is more likely to cause pain than with the more evenly distributed lesions. Pain along the line of a nerve that might be pressed on at its exit is also more probably caused by the exostosis.

Not infrequently in these cases I decide that the localization or distribution of the pain does not fit the lesions shown by the roentgen ray and go on to make some other diagnosis.

This may be of a mechanical lesion or of a coexistent infectious arthritis or myositis. An old infectious arthritis may show some changes in the adjacent bone.

With negative roentgenograms or those showing only a tilting of the pelvis and lower spine has the problem finally been reduced to a differentiation between a sprain and a toxic or infectious lesion of the joint or muscle? As noted earlier, lesions of the central nervous system and visceral reflex pain have still to be eliminated. What of faulty posture? It is usually only a predisposing cause. It must be remembered that an individual may have had a faulty posture for years but sudden gain of weight or rapid loss of strength or radical change of occupation may cause a relatively sudden onset of backache. Usually the postural fault operates by way of ptosis. As ptosis increases, with loss of tone and congestion or dilatation of the viscera, the drag causes backache. This is usually annoying rather than disabling. Not infrequently the ptosis leads to colonic stasis and so the faulty posture becomes a predisposing cause of an infectious lesion of the back rather than a mechanical one.

Careful attention to the history and to the mode of onset and course of the back pain will help to decide whether one is dealing with a sprain or a mechanical strain. For years sacro-iliac displacements or sprains have been overplayed. Then the honors were divided between lumbosacral and sacro-iliac sprains or they were simply said to be a low back sprain. Now the pendulum has swung far to the opposite side and many articles in recent literature claim that all these back pains are toxic. Myofascitis is the popular term.

As always, the truth lies between the extreme views. There are lesions purely mechanical and any associated inflammation is of a traumatic type and not at all of a bacterial type. There are many others which are purely toxic; a myofascitis or arthritis is similar to muscular or joint rheumatism in the limbs or to a toxic neuritis. In the back there is also a large group of a mixed type. Posture was a predisposing cause, or injury an exciting cause, but the toxic element is responsible for the continuance of the trouble.

The local focus may be teeth or tonsils or any other lesion that could cause an infectious arthritis. There is a strong tendency in recent literature to claim that colon stasis and colon toxemia are almost the sole cause of these painful backs. This should be very gratifying to me, since I have talked for years of the importance of considering the colon as a possible focus causing infectious arthritis. I feel that at last the colon is being overplayed, for I find that other foci, such as the teeth, may be the sole cause of some back lesions. The physician's duty is to investigate all possible foci of infection and to treat any that may seem probable causes.

In the meantime, rest is important. The patient should have sweat baths or long exposures to infra-red or other powerful lights. Salicylates and alkalis are indicated in liberal doses. I do not manipulate these patients or apply plaster casts, but I often use a reinforced corset, at first for comfort, and later, as a protection to the back when they resume work.

So far no mention has been made of the neuroses. These come in at times to disturb the diagnosis and all too often to set at naught the treatment. There is occasionally a complaint of disabling back pain which is a manifestation of hysteria in the ordinary run of cases. The greater number of them are in persons who have a damage suit in view or who are receiving accident benefits or workmen's compensation. Some are pure malingerers, but the majority have some basis of uncertainty, or fear, or loss of confidence. All too often the "bad thought" has been given them by the osteopath or the local physician who delights to differ with the company doctor. These patients usually had some real back injury to start with. Frequently it was not taken seriously and was not treated promptly by the first physician in charge. Roentgenograms were delayed. Early rest and adequate support was not provided or the patient was not followed up and encouraged and helped to resume light activity before attempting heavy work. Then the situation was aggravated by the late application of a brace and a long drawn out course of physical therapy.

Simple treatment early with assurance and close attention to the general health and morale, could have prevented the patient's becoming a "chronic" except in the patients with too broad a yellow streak or the inveterate seekers of compensation.

The treatment of acute and chronic sprains or strains is largely mechanical. Rest of the patient and partial or complete immobilization of the back is indicated. There is no medicinal value in adhesive plaster, and merely to enclose the patient in a culvert of plaster of paris is only to increase his discomfort.

Immobilization must be as nearly as possible in an anatomic position, and the pull of the adhesive plaster or the turn of the plaster bandage must be for the definite purpose of relieving a ligamentous strain and maintaining a favorable position for repair. Muscle spasm and malposition to dodge pain have usually resulted in a distorted position of the back and pelvis. In early cases this may be overcome by partial suspension, with perhaps one foot raised and the patient assisted by the hands of the surgeon. Strapping can then be applied firmly to the pelvis and lower part of the back over a properly shaped sacral pad of saddler's felt.

If the patient cannot be straightened out, a few days' rest in bed, with heat and sedatives, may gain enough relaxation to enable one to pose the patient. Some surgeons advocate extension in bed.

In more severe cases an anesthetic should be given and the muscle spasm thoroughly overcome by manipulation, and reposition to the anatomic position gained. At times it is quite a problem to decide what is the anatomic position for a certain individual. His original build must be considered and how it may have been modified by age or habit or occupation. Usually these patients need more lumbar lordosis, but a certain group should have the lordosis curve lessened. If the anesthetic has been necessary I always put on a plaster cast, using the Goldthwait frame or, sometimes, a fracture table. The cast holds securely what has been gained. Sometimes I do not estimate the position correctly and have to put on a second cast in forty-eight hours. The jacket is not considered a success unless the patient can be up in a few days. The plaster jacket is soon replaced by a leather or celluloid jacket or a back brace. The plaster cast is split and removed for the model or measurements and promptly replaced and strapped together.

Less severe cases can be put in a brace or reinforced corset at once. In all cases the lumbar and lower dorsal spine should be controlled at once. The ordinary sacro-iliac support is useful in my hands only when recovery is well advanced or as a safeguard against a relapse. However, if the brace or corset does not adequately protect the lumbosacral and sacro-iliac joints, it will be a failure. A proper sacral pad, not too big or too hard, is necessary, as well as a pelvis overstrap on all corsets.

These back braces and corsets require much more personal attention from me than do even complicated limb braces. The rigid stays must be reshaped, the pads altered or the overstrap shifted.

Almost as soon as a physician has a patient comfortable in a back support, he must begin to think of when and how he can get him out of it. If the patient is just left to go on wearing the support indefinitely it is likely to become a life sentence. It should early be removed for heat and massage and a little later for gentle exercises. If possible, the patient should soon begin to do chores or light work in the brace. Then the brace may be shortened or replaced with a lighter support or left off part of the time.

The back tends to become stiff or weak if the brace is worn too long. When the patient tries to bend, he has a little discomfort and is afraid to go on trying. The Morse sine-wave current is valuable at this stage to loosen up and strengthen the back muscles.

Patients with toxic lesions of the back imposed on mechanical disturbances naturally require a combination treatment.

A few patients who are not relieved by a brace or, if relieved, cannot get along without a brace are suitable for arthrodesing operations on the low lumbar and sacro-iliac regions.

It must be evident from the difficulty in diagnosis and treatment of low back pain that great care must be taken in the selection of cases for operation or the results will be disappointing. Failure is almost certain in long standing compensation cases and in psychoneurotic patients.

In a series of sixty-six private patients, all adults and with no medicolegal or compensation cases, the following distribution of back lesions occurred:

A roentgen examination was positive and diagnostic in twenty-one cases: Six minor fractures: five compression and one transverse processes. Seven erosive bone disease: three tuberculosis of the body of the vertebra without kyphosis; one tuberculosis of the sacro-iliac vertebra; three metastatic carcinoma in which the primary growth had not been discovered prior to my consultation. Three spondylolisthesis: two with congenital malformation, one a spina bifida occulta and one with six lumbar vertebrae with sacralization of the sixth, and a slip between the fifth and sixth lumbar vertebrae in a patient with pellagra. One unilateral sacralization of the fifth lumbar vertebra with separation and pain on the opposite side. One impaction of the transverse process of the fifth lumbar vertebra with arthritic changes. Three hypertrophic arthritis: two primary lesions with irregular bridging and one secondary to old scoliosis.

In ten more the roentgen examination was positive but showed only a predisposing cause or a lesion not the cause of pain. There were seven congenital malformations as follows: three with six lumbar vertebrae, three with spina bifida occulta, one with sacralization of fifth lumbar vertebra.

There was one case of mild spondylolisthesis and one with hypertrophic arthritis in which the real lesion was infectious arthritis, and one hypertrophic case in which a lumbosacral sprain was the cause of pain.

There were forty-five cases in which the roentgen examination was negative or showed only asymmetry of the pelvis and spine due to acute pain or posture adaptation to recurrent or chronic pain. Of these, twenty were mechanical or largely so; fifteen were infectious; eight reflex pain, and two neuroses.

The mechanical group comprised: Twelve acute or subacute sprains; one from a fall, two from motor car crashes, five from lifting, four from long or hard driving of a motor car. Five chronic or recurrent sprains; two postural strains; one postural strain with the addition of trauma.

In half of the acute sprains there was some recurrence or relapse which required treatment but which are not listed a second time.

Of the fifteen cases of infectious arthritis or myositis, nine gave no history of trauma or strain and six followed some mechanical stress.

The reflex pains were: Cord changes from syphilis, two; cord changes from pernicious anemia, one; visceral reflexes, five.

It must be admitted that there may have been some infectious element in some of the cases listed as mechanical. One cannot avoid doing anything which might help in some private cases. To a considerable extent I have tried to make the therapeutic test fairly decisive by using only mechanical measures with one group and treating foci and using drugs with the other. Physical therapy was used more or less with each group. Naturally I have sometimes started with one theory and shifted to the other as a result of failure of the first to give relief.

For contrast I am giving a series of sixty-six consecutive cases of major complaint of the back examined by me at the Research Hospital Diagnostic Clinic, a pay clinic for referred cases, mostly chronic:

A roentgen examination was positive and diagnostic in sixteen cases: tuberculosis of the vertebra, one; metastatic carcinoma, one; Hodgkin's disease, one; obscure osteomalacia of the spine, one (probably of parathyroid origin); spondylolisthesis with congenital malformation, one; postural spondylolisthesis, two; hypertrophic arthritis, seven, and infectious arthritis with bone changes, two.

A roentgen examination was positive but not diagnostic in eleven cases: congenital malformations, seven (not counted in the total); hypertrophic changes but lesion of infectious arthritis, two; hypertrophic changes but lesion of visceral reflex, one, and spondylolisthesis but lesion of infectious arthritis, one.

A roentgen examination was negative or showed only lateral asymmetry in forty-six cases: traumatic sprains, three; occupational postural strains, two; sprains followed by infectious myositis or arthritis, five; infectious myositis or arthritis, twelve; posture plus visceral ptosis, five; reflex from true visceral lesions, six; mixed with mechanical features, visceral lesions and foci of infection, ten, and psychoneuroses, three.

There were a good many cases in each of these series in which the diagnosis was difficult. In some the etiology was obscure. In others, so many possible etiologic factors were found that the choice of the most probable was difficult or could be decided only by therapeutic tests. Here is one case that illustrates this type:

Mrs. C., aged 49, had had a low backache for many years. Since an operation on the appendix and gallbladder three years before she had been badly crippled. The pain now extended from the lower part of the back into the thighs. Besides, she complained of poor circulation and of gastro-intestinal distress.

The patient was a moderately heavy woman with a fair contour of back. Forward bending caused low lumbar and sacro-iliac pain on the right. Straight leg raising caused right sacro-iliac and sciatic pain.

The complete general examination offers support for three theories. For mechanical: long history, marked congenital malformation, lumbarization of the upper part of the sacrum, and poorly fused asymmetrical sacro-iliac joints. For reflex: fixed lower uterus and pelvic tenderness. For toxic: slight arthritic pains in some other joints, some suspicious teeth, a spastic colon with some cecal fixation, and a basal metabolic rate of minus 15.

Recommendation: Hospitalization, a few days of intravenous salicylate-iodide and then the removal of suspicious teeth. Regulation of spastic colon and a course of thyroid extract. Physical therapy to the back and a corset brace with rigid back stays, special sacral pad and good abdominal lift.

If other conditions improve but the low back pains remain at the end of six months, hysterectomy and mobilization of the cecum are indicated.

306 East Twelfth Street.

ABSTRACT OF DISCUSSION

Dr. Archer O'Reilly, St. Louis: Backache is not simple but complicated, and consequently a condition that should be treated with a good deal of respect. Backache is a common symptom. Success in its treatment depends to a great extent on the care with which the patient is examined. One of the most important things is to make a careful study of the case and an accurate diagnosis. Is it traumatic or due to postural strain? Is its origin toxic or due to a definite pathologic condition? Of course, no accurate diagnosis can be made unless a roentgenogram is taken. It has been my misfortune to see a great many cases of backache that have been treated without this. A lateral and anteroposterior view should be made in every case, whether it seems serious or not; otherwise, some condition may be overlooked. A stereoscopic view is useful, but I do not think that it can take the place of a lateral view. The detail must be good, or compression fractures may be overlooked. The question of abnormalities of the lower part of the back is of interest and I feel that they are almost more common than the so-called normal. Many of these, I feel, cause little trouble, but some are predisposing factors to backstrain, and a person with an abnormality of the lower spine may more readily develop backache as a result of trauma or toxin. Good roentgenograms are essential in studying abnormalities and skill is required in interpreting them as one may be easily led astray. The roentgenogram of the lower part of the spine is tricky and one may easily see things that do not exist. A roentgenogram should be made immediately in all back injuries. I have seen a good many cases in which a diagnosis of back sprain was made and no roentgenogram taken that later showed fractures of various types. As a result of this neglect the patient was allowed to suffer unnecessarily, time was lost, and his earning power was reduced. It should seem unnecessary to mention this, but it happens time and again and I think that the medical profession is remiss in not seeing that these patients get the proper attention at the time of injury.

Dr. Fremont A. Chandler, Chicago: I want to emphasize one point. The lower part of the back may be the seat of multiple congenital anomalies, some of which may predispose to injuries and discomfort and some may have no relation to it, but low back conditions should be subdivided as accurately as possible. I have investigated these cases operatively and believe that there is a definite fracture in a great number of these cases which is almost always overlooked. All these patients show the same roentgenographic picture and the same clinical picture; that is, distress on prolonged standing. They may stand for a short time without discomfort. Prolonged standing causes discomfort in the back and also down the leg. They may walk two, three or four blocks with comfort, but when they walk ten or twenty blocks they are very uncomfortable and have to sit down. This will help in classifying many of these fractures. Dr. Willys has found such lesions in an average of 3.8 per cent of skeletons to which he had access. If that fits in with the clinical observations, this diagnosis is being missed in a vast majority of the cases.

Dr. Guy A. Caldwell, Shreveport, La.: I am sure there will be general agreement with Dr. Schauffler, especially when civil courts are in session, that every patient with back injury seems to be more or less affected by the desire to obtain a liberal settlement. I have had occasion to make reexaminations in twenty-two compensation cases from several months to several years after the claims had been settled. Fifteen, with negative roentgen observations, showed sacro-iliac symptoms of varying duration and severity; in five of the fifteen there were associated sciatic symptoms. On reexamination of the fifteen patients after settlement had been made, only one was apparently cured; eight could do only light work and were approximately 50 per cent disabled, and six were still totally disabled for hard labor. Thus, after all question of compensation had been ruled out, 40 per cent were still totally disabled, 53 per cent had 50 per cent disability, and only one was apparently cured. These figures not only are a sad commentary on the ineffectiveness of treatment but also indicate that compensation neurosis was certainly not a great factor in these cases. There were six other compensation cases reexamined after settlement in which there was roentgenographic evidence of fracture or dislocation of the fifth lumbar vertebra. Three of the patients were still totally disabled and the other three were at least 50 per cent disabled for heavy duty. The study of all these cases emphasizes the fact that negative roentgen observations in cases of low back injury are of no practical value in prognosis and treatment. The courts, most general surgeons, and some orthopedic surgeons undoubtedly place too much emphasis on negative roentgen observations. Many are prone to visualize the degree of pathologic change from the roentgenogram and to formulate the diagnosis and treatment from this false basis. Dr. Schauffler's suggestions for the treatment of cases with associated neuroses are logical and useful, but by his own admission they are often inadequate and ineffective. The small group of compensated cases which I reexamined after settlement made me feel that the neurosis was a very small factor and that no amount of psychotherapy, even the liberal use of greenback poultices, will effect a real cure in the majority.

Dr. Robert McE. Schauffler, Kansas City, Mo.: The question is, Are these fractures or are they an increase in a congenital cleft? Was there a lack of fusion there and as a result of trauma or strain was that gap increased? I have been inclined to regard them under the latter head. I remember seeing only one case that I was sure was a fracture. Two of Dr. Chandler's cases looked as though they were bona fide fractures. That they are the cause of the disability is obvious in either instance, and it is very important to look for them. Dr. Caldwell's looking up of his compensation cases is interesting and helpful, and excuses some of these chaps. I am still inclined to think that the continuing disability in at least half of the cases was not on account of the severity of the injury but because they did not get adequate treatment early or because they could not get out of the rut. The patients were afraid to leave off the brace, afraid to go back to their work because their compensation would stop, until it was too late. If there were some way to get these men at light work, if something could be done with physical therapy beyond merely baking them, really good massage, more sine wave treatment, which helps exercise these muscles, helps do away with some of the weakness and some of the fibrosis that results, I think a better showing would be made. Persistence is necessary. I remember one doctor on whom I put two different casts without relief. All his friends said it might be toxic, and the diagnostic clinic could not find anything wrong. Finally I put a third cast on him, standing in extension on the frame and partly untwisting. This gave relief and a brace completed a cure.

THE REACTION OF THE CONTENT OF THE GASTRO-INTESTINAL TRACT[*]

FRANK C. MANN, M.D.
AND
JESSE L. BOLLMAN, M.D.
ROCHESTER, MINN.

The various digestive enzymes that are poured into the gastro-intestinal tract require different chemical reactions of the gastro-intestinal content for optimal activity. These reactions vary from one definitely acid for the stomach to one neutral or slightly alkaline for the remaining portion of the gastro-intestinal tract. The changes in reaction of the gastro-intestinal content as it passes through the gastro-intestinal tract, necessitated because of the needs of the various enzymes, have formed the basis for many physiologic problems and have offered the possibility for the development of certain pathologic conditions. The actual changes in the acidity of the gastro-intestinal content at various portions of the gastro-intestinal tract and following various diets are in themselves of considerable physiologic value. The mechanism whereby the changes are graded as the content passes, for instance, from the acid secretion in the stomach to the neutral or alkaline secretion in the duodenum also raises problems of considerable physiologic significance.

Several years ago, Mann and Williamson[1] developed a method for the experimental production of peptic ulcer, based on the theoretical consideration that chemical and mechanical factors are important in the production of this lesion, and that the exposure of the ulcer-bearing area of the gastro-intestinal tract to an acid medium depended not only on the amount or concentration of the acid produced but also on the mechanism that neutralized the acid. The experimental procedures designed on these theoretical considerations were almost invariably productive of subacute or chronic peptic ulcer, characteristically similar both macroscopically and microscopically to the lesion seen in man. However, these investigators were not able to determine whether the theoretical considerations that made possible the development of a successful method for producing chronic peptic ulcer were correct. In order to determine this, it would be necessary to observe the changes in acidity taking place in the gastro-intestinal tract, particularly at the pylorus and in the duodenum, at frequent intervals over long periods of time in the fasting state and following the ingestion of various types of food. These observations should give information with regard to: (1) the variation of acidity occurring in the stomach; (2) the changes that take place at the pylorus and in the duodenum, and (3) the extent to which various types of food affect the chemical reaction of the content.

The first difficulty to overcome was in the development of a reliable method for obtaining specimens of the content of the gastro-intestinal tract at various levels. Such a method should make it possible to secure specimens from various levels of the gastro-intestinal tract repeatedly, and without affecting the normal physiologic mechanism of the gastro-intestinal tract or the general condition of the animal.

Several methods have been developed. In a limited way, it is relatively easy to determine the changes of reaction of the gastric content, by the withdrawal of specimens through a stomach tube. On the other hand, this method is limited to the study of the reaction occurring following the ingestion of food that can be withdrawn readily. Although specimens may be obtained readily from the duodenum of human beings by means of the duodenal tube, only rarely have we been able to secure duodenal content with a duodenal tube from the dog. The results of observations on such specimens were also open to the criticism that gastric content was passing through the pylorus, owing to the presence of the tube. One of the oldest and most used methods of obtaining specimens of the content of the gastro-intestinal tract is through a fistula directly into the desired portion. This method usually is not satisfactory because of leakage from the fistula, with the resulting effect on the general condition of the animal. Not only is it difficult to prevent the action of the digestive juices on the surface of the body on which they are discharged, but, as Walters and Bollman[2] have shown, characteristic changes and death almost invariably follow the formation of an external fistula of the upper part of the digestive tract. It has not been found simple to obtain the content of the intestinal tract below the first portion of the duodenum, either in the human being or in experimental research. It is possible to pull up a loop of intestine and to transpose it under the skin, and at a later time to puncture both the skin and the intestinal wall with a needle and withdraw the contents by a syringe. However, the number of specimens that can be so obtained is limited, and we have not found the method satisfactory. Experimental studies also have been made on gastro-intestinal content secured by opening the abdomen under anesthesia, ligating at various points in the gastro-intestinal tract quickly, to isolate the content in the loops between ligatures, and thus secure specimens. Such experiments are necessarily complicated by an anesthetic, and peristalsis could readily change the fluid from one portion to another while preparations for securing the material were being made.

After the various procedures mentioned had been tried, the following exceedingly satisfactory method was developed: The essentials of the method consist in isolating a loop of the terminal portion of the ileum from 8 to 16 cm. in length: maintaining the continuity of the intestine by suitable anastomosis; anastomosing the distal end of the isolated segment end-to-side to the portion of the gastro-intestinal tract to be tapped, and bringing the proximal end of the isolated loop to the skin. The site from which specimens were to be secured was thus connected to the outside with a tube of intestine. Since the peristaltic waves in the transposed loop were from the surface of the skin toward the lumen of the intestine, leakage did not occur. In this manner, by the simple insertion of a catheter through the transposed loop, it is possible to secure specimens every few minutes for many hours. Animals thus operated on have remained in excellent condition for several years. The procedure has not seemed to affect the activity of the gastro-intestinal tract. It is possible to tap the gastro-intestinal tract at any point from the cardia to the colon. It is also possible to tap it at two or more places, so that specimens can be obtained simultaneously at different points.

With a satisfactory method at hand for obtaining specimens of the gastro-intestinal content we have observed the changes in reaction that occur in the fasting animal following various diets, and following the carrying on of the therapeutic procedures that have been used clinically for changing the reaction of the gastro-intestinal content.

The hydrogen ion concentration of the samples of intestinal content was determined by the quinhydrone gold electrode with a Leeds and Northrup potentiometer. This method was found to be advantageous in several respects: a few drops of intestinal content are sufficient for a determination; the determination can be made in less than a minute after withdrawal of the sample, and exposure of the sample to loss of carbon dioxide is reduced to a minimum; the method is consistent and gives results that are slightly higher (0.05) than determinations with the hydrogen electrode. One disadvantage of the quinhydrone method in our hands has been that we are unable to obtain reliable results if small amounts of blood contaminate the sample of intestinal content. This error is greater than could be accounted for by the buffer action of the blood present, and for this reason we have discarded any sample of intestinal content that contained a trace of blood.

All of our results have been obtained with normal-appearing, healthy dogs which were maintained on our usual kennel diet except for the days when the tests were performed. The test was as follows: Food was withdrawn from the animals' cages at 4 p. m. the day previous to the test; at 7:30 a. m. the animals were allowed thirty minutes of outdoor exercise away from food; at 8 a. m. the animals were taken into the laboratory and samples of the intestinal content were obtained at intervals of fifteen minutes; at 9:30 a. m. the animals were fed and subsequent samples were withdrawn at intervals of fifteen or thirty minutes until 4:30 p. m., when the animals were returned to the kennels. Two or three samples were obtained the following morning, before the animals were allowed the routine diet.

RESULTS

Stomach.—In the fasting animal, the small amount of gastric juice present in the stomach was usually found to be of about p_H 1.5 to 2.0. Occasionally readings almost neutral, p_H 5.5 to 6.9, were obtained, particularly if the routine procedure was broken and the samples were obtained before the dog was brought into the laboratory. After a meal, the gastric content immediately assumed a reaction depending somewhat on the nature of the food, but with most diets a reaction approaching neutrality was reached. The gastric content rapidly became more acid; within ten or twenty minutes the p_H usually reached about 4.0. About two hours after feeding, the acidity of the gastric content was about 2.0, but the increase in acidity was irregular and at times was found to be reduced, as though some neutralizing factor had been introduced. From two to four hours after a meal, the acidity of the gastric content usually approached p_H 1.5 and remained in this neighborhood for the rest of the day, except for a few brief periods of neutralization, in the course of which it sometimes rose as high as p_H 4.0.

Duodenum.—In the fasting dog the duodenal content was usually found to be of about p_H 7.6, with occasional variations as low as p_H 5.6. In fasting dogs in which high acidity of gastric content was found, p_H 1.5, occasional determinations in the duodenum gave results as low as p_H 2.0, but readings taken a few minutes later were higher again. After a meal, the p_H of the content of the duodenum followed somewhat the course of that of the stomach. In the first thirty minutes the p_H usually remained around 7.2. After this time, more rapid fluctuations appeared; most determinations were in the region of p_H 5.5, with frequent values as low as p_H 4.6. About two hours after feeding the p_H began to rise slightly, but occasionally readings indicating considerable acidity, p_H 1.8, were obtained. The general tendency was toward neutrality and the rise was gradual to a point about p_H 6.8. The alkaline readings, characteristic of fasting, p_H 7.6, were seldom obtained until six hours had elapsed after feeding, and frequently more than twelve hours elapsed before this reading was obtainable. Variations in a more or less normal diet did not produce marked changes in the acidity of the duodenum except as they affected the acidity of the stomach. After a meal of raw meat the duodenal acidity was only slightly greater than it was after a meal of milk.

Jejunum.—The content of the jejunum from 30 to 50 cm. below the ligament of Treitz was slightly alkaline in the fasting animal and did not appear to be greatly influenced by the diet. Usually the p_H was from 7.0 to 7.6, but in several instances, in trained animals, the values were as low as p_H 5.6. After feeding, there was a slight change in the p_H of the jejunal content, with a tendency for it to become more acid, usually to p_H 6.8 to 6.2, five or six hours after feeding. Shortly after this time, the p_H again approached the fasting level, but it seldom reached this point on the day that the test meal was taken. On rare occasions, from two to four hours after a meal, an individual determination showed the p_H to be as low as 4.0, but a few minutes later the usual readings were obtained.

Ileum.—The content of the ileum 100 cm. below the ligament of Treitz, and also 70 cm. above the cecum, was usually alkaline in the fasting animal; the p_H was from 7.0 to 8.0, with an exceptional reading as low as p_H 5.6. The diet of the preceding day had a slight influence on the acidity of the ileac content, but there appeared to be other factors which had a greater influence. After a meal there was little change in the p_H of the ileac content. There was a slight tendency toward acidity, to the degree of p_H 6.5, and an exceptional reading was sometimes found as low as 5.4. These rapid fluctuations, however, were almost entirely absent from the ileum. We found the reaction of the content of the terminal portion of the ileum to be similar to that reported by Dean, that is, a p_H usually above 7.5 with an occasional reading as low as 6.0.

Colon.—The acidity of the content of the middle portion of the colon in the fasting animal depended somewhat on the nature of the diet. With a diet free from meat, or with a mixed diet, the p_H was usually found to be about 7.4, but at times it was found to be as low as 6.5. With a diet rich in carbohydrates the acidity was sometimes found to be as low as p_H 5.5. After a meal there was little change in the acidity of the colon within the first four to six hours, after which time very slight increases in acidity were sometimes found after a diet rich in protein or after a mixed diet. With a diet rich in carbohydrate, however, the p_H sometimes reached 4.4, although the more common reading was about p_H 6.0.

Therapeutic Diets.—The changes in acidity of gastric content brought about by the introduction of food and the persistence of high acidity in the stomach after the food had passed, clearly indicated that frequent feedings tended to reduce the acidity of the gastric content. With feedings of milk and cream, 120 cc. every two hours, high acidity just began to develop in the stomach of the normal dog at the end of two hours. When only half of this amount of milk and cream, 60 cc., was given, high acidity was found usually within thirty minutes after feeding. In the duodenum high acidity was immediately reduced, when any of the foods we used were given by mouth. Milk, cream and fine particles of meat were found in the duodenum a few moments after such food was taken. High acidity did not develop in the duodenum after a meal except as the food passed in from the stomach. In the same way, 120 cc. of milk and cream every two hours prevented high acidity of the duodenal content except just at the end of the period, although half of this amount every two hours had little effect. With the administration of alkalis, gastric and duodenal acidity was reduced so that no highly acid values were obtained.

COMMENT

It is not appropriate to review here the large amount of work that has been done on the chemical reaction of the gastro-intestinal content. Attention should be called to the possibility that the variation in results obtained is due to error dependent on the method of securing the specimens. Although it is not safe to assume that any surgical procedure on the gastro-intestinal tract ever leaves it physiologically normal, in view of the fact that we were never able to demonstrate any variation from the normal in the general condition, motility of the gastro-intestinal tract, and so forth, in our animals, we feel justified in considering that our data represent true physiologic conditions. The difference in opinion in regard to the value of the various methods of estimating the acidity of the gastro-intestinal content need not concern us because we are interested only in relative values, and the method employed was fully adequate for our purpose.

A few possible sources of error should be mentioned. A most important factor to evaluate in the experiment was the change in activity of the gastro-intestinal tract associated with the training of the animal. It is undoubtedly true that the secretory and motor activity of the gastro-intestinal tract is influenced by innumerable factors. Our observation showed that the acidity of the gastric content of the trained dog, in a fasting condition, was considerably higher when the specimen was secured in the animal's cage than it was a few minutes later, when the animal was in the observation room, preliminary to the feeding. However, it should be clearly recognized that all observations were made under normal physiologic conditions.

A few of our observations are of sufficient importance to be emphasized. One of the most striking phenomena is the high acidity of the small amount of the gastric content in the fasting animal. Although the rapidity of the changes that occur at the pylorus, in the stomach and in the duodenum might be expected, they are of greater magnitude than would be anticipated. The changes in the reaction of the content of the small intestine are less than would be expected. The constancy of the reaction noted in this portion of the digestive tract is one of the most outstanding observations. Finally, it should be noted that the various foods did not produce such marked changes as previous work would indicate should be found, whereas administration of alkalis was effective in reducing the acidity.

SUMMARY

A method was developed for repeatedly securing, under normal physiologic conditions, specimens of the gastro-intestinal content at various levels of the tract. Estimation of the acidity in the fasting animal showed that the gastric juices are usually strongly acid, p_H 1.5 to 2.0, but may be at times almost neutral. The content of the duodenum, jejunum, ileum and colon is usually found to be alkaline, p_H 7.0 to 8.0, with the exception that the content of the duodenum may be found to be acid when highly acid values are found in the content of the stomach. Following a meal, the acidity of the content of the gastro-intestinal tract depends largely on the development of acid in the stomach. Short periods of high acidity of content are common in the duodenum and less common in the small intestine, the greater the distance from the pylorus. The usual reaction in the small intestine, after a meal, is close to neutrality, p_H 6.5 to 7.5. The content of the colon is usually slightly alkaline but may be slightly acid, especially following a meal rich in carbohydrate. Dietary measures may greatly alter the acidity of the content of the gastro-intestinal tract.

ABSTRACT OF DISCUSSION

Dr. A. C. Ivy, Chicago: The work that Dr. Mann and Dr. Bollman have done is obviously of fundamental importance not only from the standpoint of the effect of diet on the reaction of the intestinal contents as related to gastrojejunal ulcer, but also as it is related to gastro-intestinal disease in general and to the more fundamental phenomena of the mechanisms concerned in intestinal digestion and absorption. So far as the method is concerned, I can testify that the fistula method used by Dr. Mann is an excellent one and is the best method I know of for use in experimental animals. Dr. Mann told me of this method some three years ago and I have been using it in the laboratory in a number of different types of experiments, with excellent results. The animals remain in excellent condition over long periods of time. The only trouble that I have observed is the occasional occurrence of an intra-abdominal hernia. I should like to ask Dr. Mann to state his objection to the method of Dr. Lloyd Arnold, who used subcutaneous transplanted loops. As I recall Dr. Arnold's work, he made practically the same observations so far as acidity is concerned as were reported by Dr. Mann. It is true that in these transplanted loops there is some interference with motility, but as I have observed these transplanted loops, one can say there is no stasis. I should also like to ask Dr. Mann if in his studies he noticed any effect of hot weather on the reaction of the intestinal contents.

Dr. F. C. Mann, Rochester, Minn.: In answer to Dr. Ivy's question, there is no serious objection to Dr. Arnold's method. We have used it. However, we wish to obtain specimens in much larger numbers than is possible if the loop is entered repeatedly through the skin. For instance, in some of our experiments we have taken as many as 1,000 specimens of intestinal contents during the day, which, I think, would not be possible with any other method now in use. Also, unless a very large needle is used, difficulty will be encountered at times if the contents contain large particles.

Word Sparing Assertions.—An interesting side light is cast on the progress of medical enlightenment by the tenacious life of medical texts. Galen's writings remained standard for over a thousand years. One text of the seventeenth century is reported as having served its purpose for fifty years. Today a medical text is outworn in five years. If the reader ventures to look into original documents he will note the wordiness and deliberation of earlier writers as compared with the word-sparing assertions of the present. And with this change he will note that that prolonged rationalizing about dubious observations disappears with fact-gathering and experiment.—Oliver, W. W.: Stalkers of Pestilence, New York, Paul B. Hoeber, Inc., 1930.

INCIDENCE OF BROMIDE INTOXICATION AMONG PSYCHOTIC PATIENTS *

CARL P. WAGNER, M.D.
AND
D. ELIZABETH BUNBURY, M.B.
Commonwealth Fund Fellows at the University of Colorado Psychopathic Hospital
DENVER

For some time we have been impressed by the number of patients admitted to the Colorado Psychopathic Hospital showing symptoms of a frank delirium, or patients suffering from some major psychosis with evidence of toxic components. In some cases the source of the toxin could not be determined, but in others, either at the time of admission or after their recovery, we were able to obtain a history that they had taken large quantities of bromides or some other sedative.

Frequently in the literature attention has been called to the fact that patients develop a toxic delirium following the long continued or excessive dosage of bromides. A thorough review of the literature on this subject has recently been given by Dr. Oscar Diethelm.[1] One writer[2] reports bromide intoxication in an entire family consisting of five adults, two small children and one nursing child, when sodium bromide was accidentally substituted for sodium chloride in the household. The physical symptoms are mentioned in practically every standard textbook in therapeutics or pharmacology, and some mention the undesirable mental symptoms due to overdosage. We feel that most of them, however, give too limited space to the mental manifestations. Sollmann's[3] remarks are quite representative:

> Fairly large doses of bromides depress the psychic functions and the reflexes, leading to a condition of dulness and apathy, which conduces to sleep, particularly in nervous insomnia. . . . The effects occur only slowly and are correspondingly lasting. Continued administration of large doses results in bromide acne and other symptoms analogous to iodism. . . . Acute bromide poisoning is rare, occurring only after enormous doses.

Since March, 1928, a determination of the bromide content of the blood serum has been a part of the routine in the examination of all patients admitted to this hospital. This paper is based on a study of the first thousand consecutive cases so examined. The determinations were made with the Wuth[4] comparator. The test is simple and, although Dr. Diethelm[1] considers the Hauptman modification of the Walter method more accurate, we consider that the former method gives determinations accurate enough for clinical purposes. Dr. Diethelm's chief objection is that in the higher concentrations the standards on the Wuth comparator do not estimate differences of less than 100 mg. per hundred cubic centimeters. This we feel is unimportant because in our series nearly all patients with a blood bromide of 200 mg. per hundred cubic centimeters showed symptoms of intoxication, so that accurate determination between 200 and 300 mg. is of academic interest only, not of clinical importance.

Of the thousand cases examined, 7.7 per cent (table 1) showed bromide in the blood serum in a concentration of 75 mg. per hundred cubic centimeters and over. Of these, thirty-three, or 42.85 per cent (table 2), had received the bromide on a physician's prescription; fourteen, or 18 per cent, had taken "patent" medicines; and in thirty, or 38.95 per cent, the source of the drug remained undetermined, but undoubtedly these patients had also taken "patent" medicines, although most of them denied that they had taken medicine of any kind, even when they were confronted with the fact that their illness was due to drug intoxication. Of course, the drug intoxications produced by bromide prescribed by physicians could have been prevented had the physician been more familiar with the untoward mental symptoms of bromide overdosage, or if he had been willing to make a blood examination according to Wuth's simple method.

TABLE 1.—*Incidence of Bromide Intoxication*

Number of Patients Examined	Patients With Bromide in Serum	
	Number	Per Cent
1,000	77	7.7

TABLE 2.—*Sources of Bromides*

Source of Drug	Number of Patients	Per Cent of Patients with Bromide in Serum	Per Cent of Total Number Examined
Prescribed by physician..........	33	42.85	3.3
Undetermined....................	30	38.95	3.0
"Nervine"........................	6	7.79	0.6
Other "patent" medicine.........	8	10.39	0 8

In seventen, or 22.08 per cent, table 3, admission to the hospital was sought entirely on account of drug intoxication. Fortunately, most of these patients recovered before or shortly after leaving the hospital. However, two cases terminated fatally, and in these we feel that death was due to the indiscriminate use of bromides only. Both of these patients showed a bromide concentration of over 300 mg. per hundred cubic centimeters of blood. On admission, both had been under the care of a physician and had been taking bromide on prescription. Five other cases terminated fatally. One of these, a patient with dementia paralytica, showed only 75 mg. per hundred cubic centimeters, and we do not feel that the bromide contributed toward his death. The four remaining patients, one with cerebrospinal syphilis, one with senile dementia, and two with cerebral arteriosclerosis, died of cardiac decompensation. In these we feel that the bromide contributed toward their death in that the excitement due to delirium aggravated the decompensation.

TABLE 3.—*Pure Drug Intoxications*

	Number of Cases	Per Cent of Cases Showing Bromide	Per Cent of Total Cases Examined
Pure bromide intoxications......	10	12.99	1.0
Recovered....................	4	5.19	0.4

Died..........................	2	2.59	0.2
Mixed drug intoxication.........	7	9.09	0.7
Recovered	5	6.49	0.5
Improved........	2	2.59	0.2
Died	0	0.00	0.0

Table 4 shows the incidence of bromide intoxication in the various psychotic conditions. Surprisingly enough, it was highest in those patients (pure bromide and mixed drug intoxication, seventeen cases) who showed no underlying psychotic condition after elimination of bromide. These patients consisted for the most part of that type of individual who is unable to make an adequate social adjustment and who resorts to alcohol and drugs as an escape from the situations in life which he considers intolerable. Of the patients with definite psychotic manifestations, the psychoneurotic ones ranked first. This is to be expected, as this type of patient resorts to drugs as a relief from symptoms. Eleven of these psychoneurotic patients had a bromide concentration of 125 or less. The other one had a concentration of less than 200 mg. None of these patients showed symptoms of intoxication. In the depressive group, which ranked second, there were three patients with a bromide concentration of 125 mg. or less who showed toxic symptoms. These three patients had passed middle age and there was some evidence of arteriosclerosis and general debility. In the two schizophrenic patients who showed toxic symptoms with a bromide concentration below 125, nothing could be demonstrated which would account for the delirium other than the bromide. This makes it appear likely that these patients had a special idiosyncrasy for bromide. It will be noted that in all of the organic group outside of cases of epilepsy there were a large number that showed toxic symptoms even with the lower concentrations. It might be suggested that since the organic mental symptoms and toxic symptoms are very much alike, some of these patients were considered toxic when in reality the symptoms were due to the underlying psychotic condition. To eliminate this factor we considered only those patients toxic who showed considerable improvement following elimination of the bromides.

In table 5 the patients were grouped according to age in decades. This shows that most of the patients below the age of 50 failed to show toxic symptoms in the concentration below 200 mg. per hundred cubic centimeters, while in the age group over 50 most of the patients showed evidence of intoxication, even in the low concentrations. In the entire group of seventy-seven patients only two with a bromide concentration of more than 200 mg. per hundred cubic centimeters showed no toxic symptoms, so that these two patients may be considered to have a special tolerance for bromide. For practical clinical purposes we think that *a concentration of 200 mg. per hundred cubic centimeters of blood should be considered toxic*, and when bromides are used the concentration should be kept below this point to avoid untoward effects. When the bromide concentration rises above 200 the patients usually begin to show some evidence of toxicity, usually first manifested by an increased restlessness with disorientation followed by paranoid trends, hallucinations, and apprehension. As the concentration increases to 200 or over, physical symptoms, such as *tremor of the hands, lip and tongue, with speech defect*, ataxia and finally stupor appear. Contrary to the accepted idea, we found acne to be comparatively rare. If the concentration goes much above 300 mg. we feel that the life of the patient is endangered.

In these high concentrations the delirium may mask completely any underlying psychotic condition. We are presenting briefly three illustrative cases; one a pure bromide intoxication; the other two respectively an organic psychosis and a functional psychosis, both with superimposed bromide intoxication:

CASE 1.—A man, aged 47, married, a traveling salesman, was admitted with a complaint of confusion. He developed a genital sore, went to a hospital and was there four weeks. While there he was nervous, irritable and restless, and was given many sedatives, but his nervousness increased. On admission to the Psychopathic Hospital, he was semistuporous, disoriented, showed numerous vaguely formulated delusions, fears of venereal disease and dying, and reacted to auditory hallucinations. Physical examination revealed speech defect, irregular pupils, sordes, furred tongue, injected throat, irregular pulse, severe genital lesion—much excoriated, edematous and exquisitely painful—and normal reflexes. Laboratory examination revealed blood bromide 350 but otherwise was negative. The genital lesion was considered probably chancroidal with extensive superimposed infection. With eliminative and nutritive therapy and bland local applications, his physical and mental condition cleared rapidly. He was discharged much improved at the end of a month with a bromide of 125, to continue his convalescence at home.

This case illustrates one of pure bromide delirium. The patient entered the hospital semistuporous, considerably dehydrated and in a very weak condition. Elimination was first started by forcing fluids and colonic irrigations. Sodium chloride in a dosage of 15 grains (1 Gm.) three times a day speeds up the elimination considerably; but as the salt usually liberates the bromide from the tissues more rapidly than it can be eliminated by the kidney, we frequently see a rise in the blood bromide and an exacerbation of toxic symptoms for a few days. In this case we refrained from giving salt for about ten days until the patient had improved somewhat physically. Then he was given sodium chloride in the dosage mentioned and he showed rapid improvement.

Case 2.—A man, aged 34, single, was admitted to the hospital with a complaint that "he was raving, thought that someone was after him." He had had a chancre at 15, and had received four injections of arsphenamine. He had an operation for gastric disorder six weeks before admission, after which he became afraid of people and thought that the police were after him. On admission he was confused, very apprehensive and emotionally unstable, incoherent, had the delusion that he was to be killed and was paranoid against his brother. Physically, the principal observations were: speech defect, marked acneform eruption on face, left pupil larger than right and fixed to light, teeth in bad condition, pharynx injected, anterior cervical adenopathy, abdominal reflexes absent, and knee jerks hyperactive. Laboratory reports revealed: blood bromide, 150; cerebrospinal Wassermann reaction, 4 = 4; gold curve, 3335430000; protein, 70; cells, 23. He was inoculated with malaria and five days later developed a rise in temperature to 105 F., which persisted for thirty hours. The malaria was therefore terminated. At the end of this time his mental condition was unchanged and he was placed on eliminative and nutritive treatment. He improved rapidly, and was fairly clear mentally when discharged after two months in the hospital.

This case illustrates an organic condition accompanied by a bromide delirium. The diagnosis of dementia paralytica was made at another hospital and the patient was transferred here for treatment with malaria. As the bromides were eliminated the patient gradually improved and was discharged two months later to resume his former activities. He has been getting along well but is in the hospital at this time, one and one-half years later, as a voluntary patient for a course in malarial therapy. Wassermann examination of the blood and spinal fluid continues positive.

Case 3.—A woman, aged 33, married, a housewife, was admitted to the Colorado General Hospital with thirteen somatic complaints. Complete examination gave negative results and after psychiatric consultation she was transferred to the Psychopathic Hospital. She stated that she had been depressed for four months, had heard people calling her names, was confused and disoriented, and showed hallucinations, both auditory and visual, the latter consisting of animals and birds. As a result of her hallucinations she had disturbed periods with marked apprehension. She was depressed, self-condemnatory and thought she was being punished with cancer. Talk was retarded but relevant and coherent. Physically, the chief observations were marked loss of weight; facial acne; tonsils and pharyngeal walls inflamed; systolic murmur present but no cardiac decompensation; abdominal and knee reflexes hyperactive; unsustained ankle clonus. Laboratory reports showed: blood bromide, 100; other results negative. The patient was placed on an eliminative and nutritive treatment, whereupon the clouding of the sensorium disappeared and the condition became typical of an affective disorder of a depressed type. Under psychotherapy and an activity regimen, she improved both physically and mentally, and at the end of two months was discharged markedly improved to continue her convalescence at home with visits to the outpatient department.

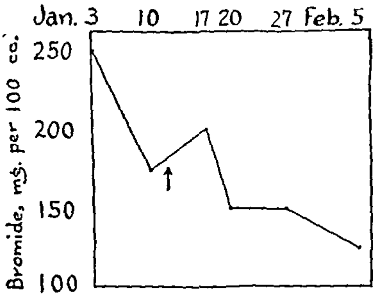

Chart 1.—Rate of elimination in an arteriosclerotic patient with bromide intoxication. Arrow indicates dosage of sodium chloride. On discharge, February 5, the condition of the patient was improved.

This patient was admitted to a general hospital with the depression almost completely masked by a toxic delirium. She was unable to tolerate bromides, perhaps on account of marked dehydration and cachexia, and developed a delirium with a bromide concentration of only 100 mg. per hundred cubic centimeters. After elimination of the bromides she presented a clinical picture of pure depression from which she had practically recovered at the time of discharge.

COMMENT

The treatment of bromide delirium is chiefly supportive and eliminative. The patients are given an abundant diet and large quantities of fluid. The oral administration of sodium chloride, about 15 grains (1 Gm.) three times a day, increases the bromide elimination. However, if patients show marked evidence of debility and dehydration and are in a weakened condition, we feel that it is inadvisable to give sodium chloride as it liberates the bromide from the tissues faster than it can be eliminated by the kidneys. As a consequence the blood bromide usually rises slightly and there is an exacerbation of the toxic symptoms which may prove fatal. If the patient has a blood bromide concentration of around 300 mg. per hundred cubic centimeters of blood, we feel that it is inadvisable to administer sodium chloride until we have had an opportunity to build up the patient physically to some extent.

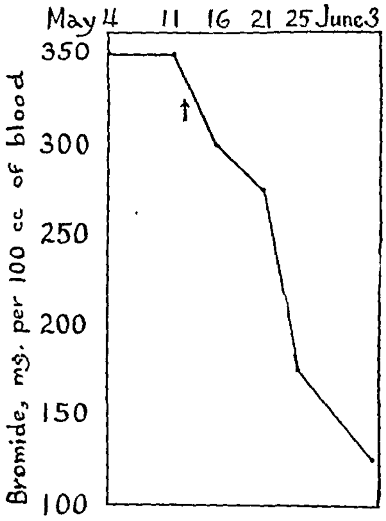

Chart 2.—Rate of elimination in an arteriosclerotic patient with bromide intoxication. Arrow indicates dosage of sodium chloride. On discharge, June 3, the patient had recovered.

Chart 1 shows the rate of elimination in a patient 59 years of age with marked evidence of arteriosclerosis. The original bromide concentration was 250 mg. per hundred cubic centimeters of blood. He was treated with elimination without administration of sodium chloride until the blood bromide concentration reached 175 mg. Sodium chloride was then given and there was a rise in blood bromide to 200 mg. per hundred cubic centimeters of blood followed by a gradual decrease to 125 mg., which was reached thirty-three days after admission.

Chart 2 shows the bromide elimination in a patient, aged 47, whose circulatory and excretory systems were in good condition. He was quite weak on admission and we refrained from giving salt for twelve days, after which he was given sodium chloride, 15 grains (1 Gm.) three times a day, without any rise in blood bromide. Obviously the kidneys were able to eliminate the bromides as fast as they were liberated from the tissues. This patient's bromide concentration in the blood dropped from 350 mg. per hundred cubic centimeters of blood to 125 mg. of blood in twenty-nine days. Comparing charts 1 and 2 it appears that bromide elimination is markedly hampered by a condition of general arteriosclerosis, and as a consequence patients showing evidence of arteriosclerosis have a decreased tolerance for bromide.

In 500 of these cases we also made bromide determinations of the cerebrospinal fluid. Bromide concentration of the spinal fluid ranged from 50 to 100 mg. per hundred cubic centimeters below that of blood. We do not feel that the information gained from the spinal fluid estimation is of enough clinical value to warrant its use. If, in addition to the fluid taken for Wassermann, chemical, and gold curve determination, fluid is also withdrawn for bromide estimation, this is enough to cause the incidence of post-lumbar puncture headaches to increase considerably.

We do not wish to leave the impression that we consider bromide harmful or even useless as a therapeutic agent. Any one who has had occasion to use bromide realizes that it can be an effective and valuable sedative. We do believe, however, that bromides are used much too indiscriminately and frequently produce harmful rather than beneficial effects. These harmful effects of bromide could be reduced to a minimum if physicians recognized the undesirable mental symptoms of bromide intoxication and were willing to use the simple method described by Wuth[4] for determining the bromide concentration in the blood.

CONCLUSIONS

1. Although bromide is a useful and effective sedative, it is far from harmless if used at all indiscriminately, as is shown by the fact that of 1,000 routine admissions to the Colorado Psychopathic Hospital 77 showed an appreciable amount of bromide in the blood serum. In 44 of these the mental symptoms were due to or increased by bromide.
2. Undesirable mental symptoms can be reduced to a minimum if the physician will be on the outlook for exacerbation of mental symptoms during bromide administration or if he is willing to make determinations of bromide concentration in the blood.
3. Special care should be exercised in the administration of bromide in cases of organic nervous disorders, particularly those in which the excretory or circulatory functions are impaired.

THE TREATMENT OF CARCINOMA OF THE BLADDER BY SURGICAL DIATHERMY

A REPORT OF ONE HUNDRED AND NINE UNSELECTED CASES *

HERMAN L. KRETSCHMER, M.D.
CHICAGO

In the evaluation of any therapeutic agent it is absolutely necessary that two conditions be fulfilled:

1. It should be the only agent used, since the use of more than one agent only serves to complicate the problem of determining to what extent each of the agents used was responsible for the recovery of the patient.
2. In order to determine accurately the value of surgical diathermy, it is necessary that all cases, "early as well as late," be treated with the particular agent under consideration. To reserve the early cases for resection and to use diathermy only in the far advanced and hopeless cases evidently is not giving this therapeutic agent an "even break."

For these two reasons the cases in this group were treated by means of only one agent; namely, surgical diathermy through the open bladder. In some of the early cases the temptation to perform a resection was exceedingly great, and in some of the far advanced cases the temptation to resort to radium instead of to diathermy was equally great; but had I yielded, this sort of uneven or unequal selection of cases would obviously not have determined the accurate value of this form of treatment. Therefore, in order to determine the exact value of surgical diathermy no selection of cases as operable or inoperable was made.

Table 1.—Age of Patients

Years	Number of Cases
30 to 40	3
40 to 50	13
50 to 60	32
60 to 70	42
70 to 80	17
80 to 90	1
Not stated	1
Total	109

Some of the patients who suffered from recurrences were operated on a second time; others refused to submit to a second operation and were treated by high voltage roentgen therapy or by radium.

It should be added that this paper is based on an unselected series of 109 cases of primary carcinoma of the bladder.

SEX

There were eighty-seven males and twenty-two females in this series. It is apparent from this particular group of cases that carcinoma of the bladder is practically four times as frequent in men as it is in women.

AGE

An analysis of the records shows that the youngest patient in this group was 35 years of age and the oldest, 82 years.

HEMATURIA

In 100 cases in this series, gross blood in the urine was noted by the patients. Gross bleeding as a symptom of great importance cannot be emphasized too often. A number of physicians still regard this symptom as of minor importance and administer some sort of local or internal treatment instead of bearing in mind that gross bleeding should always be interpreted as meaning the presence of a serious organic disease and that the first thing to do is to determine the origin of the bleeding and then the cause. Not only was hematuria a common and prominent symptom but in the largest number of cases (sixty-three) it was the first symptom noted by the patient.

Table 2.—*First Symptom Noted by Patient*

Symptom	Number of Cases
Hematuria	63
Frequency of urination	26
Nocturia	9
Burning	3
Urgency	2
Pain in	2
Acute retention of urine	1
Dysuria	1
Dribbling	1
Not stated	1
Total	109

URINALYSIS

A review of the urinary observations in this series showed the presence of pus in ninety-nine cases, albumin in eighty-five and blood in seventy-five cases.

---

* From the Presbyterian Hospital.

* Read before the Section on Urology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

TYPES OF ORGANISMS

The following organisms were isolated in culture: *B. alcaligenes*, *B. coli*, *B. coli* and *B. proteus*, *B. coli* and *Staphylococcus albus*, *B. proteus*, *B. pyogenes*, *Eberthella* group, *Staphylococcus albus*, *Streptococcus hemolyticus* and *Streptococcus viridans.*

DIAGNOSIS

The preoperative diagnosis of carcinoma of the bladder was made from the cystoscopic examination and coupled with a complete history and physical examination, urinary examination and cystograms, and was verified by the removal of pieces of tissue at the time the bladder was opened. Cases presenting the picture of benign papillomas were subjected to fulguration through the cystoscope and hence are omitted from this report.

In some instances in which the element of doubt arose at the time of the cystoscopic examination, pieces were removed with the cystoscopic rongeur for a careful histologic study. Although it is possible to miss a malignant area in an apparently benign tumor, in the cases in which a malignant condition was suspected and in which the histologic report showed a carcinoma the cystoscopic diagnosis of malignant tumor was verified.

Table 3.—*Causes of Death in Group 1*

	Number of Cases
Pulmonary embolism	7
Pneumonia	4
Acute suppurative pyelonephritis	3
Anuria	3
Uremia	2
Acute dilatation of the heart	2
Acute dilatation of the heart and stomach	1
Carcinomatosis	2
Chronic myocarditis	1
Total	25

In borderline or doubtful cases, cystograms were made in order to determine the presence of infiltration of the bladder wall. The use of the cystogram has certain limits. In case the malignant condition is in the periphery of a papilloma with only slight involvement of the pedicle and no infiltration of the bladder wall, the cystogram would necessarily be normal.

RESULTS

For the purposes of analyzing the results obtained, the cases may be grouped under the following four headings:

Group 1, operative deaths.
Group 2, patients who died after they left the hospital.
Group 3, patients who may be considered as cured.
Group 4, recurrences.

OPERATIVE DEATHS

As previously stated in this paper, early as well as late cases were treated in the same way and no attempt was made to select the cases. In the operative deaths all patients are included who died in the hospital, irrespective of the time they lived between the operation and the time of death. Twenty-five patients, or 22.9 per cent, died in the hospital. The pulmonary causes of death head the list with seven cases of pulmonary embolism (28 per cent) and four cases of pneumonia (16 per cent). The pulmonary complications, therefore, were responsible for 44 per cent of the deaths. The urologic complications formed the second largest group, or eight cases (32 per cent), with anuria three cases, suppurative pyelonephritis three cases and uremia two cases. Two patients died within twenty-four hours after the operation. The hemoglobin was 20 and 22 per cent, respectively, and there was great distention of the bladder due to blood clots. Operation in each case was advised to stop the bleeding and to remove the clots. Another patient died suddenly thirty-six hours after the operation; an autopsy showed an acute dilation of both the stomach and the heart. In this group there were twenty-one males and four females and the average duration of life after operation was twenty-two days. Table 3 shows the cause of death in this group.

Table 4.—*Causes of Death in Group 2*

	Number of Cases
Carcinomatosis	26
Pneumonia	5
Suppurative pyelonephrosis	3
Uremia	3
Chronic myocarditis	2
Chronic nephritis	1
Cerebral hemorrhage	1
Edema of lungs	1
Toxemia	1
Tuberculous meningitis	1
Unknown	1
Total	45

PATIENTS WHO DIED AFTER THEY LEFT THE HOSPITAL

The cases in groups 1 and 2 all showed extensive carcinomatous disease of the bladder and the operation was more or less palliative in nature. In many cases there was extension of the carcinoma beyond the confines of the bladder with involvement of the surrounding structure.

In group 2 there were thirty-eight males and seven females. The longest duration of life was five and one-third years and the shortest duration was five months in two cases. The average duration of life between the operation and the date of death was eighteen and one-half months.

Table 4 shows the causes of death after the patients left the hospital.

PATIENTS WHO MAY BE CONSIDERED AS CURED

In group 3 there are twenty-three patients who are living and well; that is, free from symptoms and with normal urine. All these patients were requested to return for cystoscopic examinations or, in case they lived at distant points, they were to have cystoscopic examinations made by competent urologists. Unfortunately, it was not always possible to convince some of them of the necessity of repeated cystoscopic examinations and particularly to convince them of the value of a recent cystoscopic examination; hence, in some cases reported here the last cystoscopic examination is not of recent date. The length of time in which the patients in this group remained free from recurrence as determined by the last cystoscopic examination is shown in table 5.

In this group there were seventeen males and six females. The average age was 58 years and the average duration of cure, so far as one may speak of cure, was 4.65 years.

PATIENTS LIVING BUT HAVING RECURRENCES

In group 4 there are twelve patients: seven males and five females. These patients had recurrences, as was proved by the cystoscopic examination in some instances. But when this procedure was not possible, it was assumed that recurrences were present in view of a return of symptoms such as painful and frequent urination, with blood, pus or bacteria in the urine, the history of loss of weight, the presence of a suprapubic fistula, and infiltration of the base of the bladder as determined by means of a rectal or vaginal examination.

One of the difficulties in treating carcinomas of the bladder arises from the fact that the tumors frequently involve or are located in the region of one or both ureters, and this fact probably exerts its influence on the mortality rate as well as on the end-results.

Table 6.—*Ureteral Involvement*

	Number of Cases	Per Cent
Involvement of right ureter	25	23.14
Involvement of left ureter	27	25.00
Involvement of both ureters	15	13.88
No involvement of ureters	41	37.90
Not stated	1	
Total	109	

A review of this series of cases bearing on the frequency of the ureteral involvement is presented in table 6.

As will be seen, there was involvement of the right ureter in twenty-five cases, or 23.14 per cent, of the left ureter in twenty-seven cases, or in 25 per cent, and of both ureters in fifteen cases, or 13.88 per cent. In forty-one cases, or 37.9 per cent, there was no involvement of the ureters. In one case the records did not give any information on this point.

Unforunately, four patients cannot be located; hence, instead of reporting end-results on 109 patients that have been operated on, I am able to report on only 105 cases.

SUMMARY

1. A group of 109 unselected cases of carcinoma of the bladder were studied.
2. All of the cases were treated with a single agent, namely, surgical diathermy.
3. In seventy cases, or practically two thirds of the cases seen, the condition was far advanced and the results from the standpoint of cure were highly unsatisfactory and the mortality rate was high.
4. In twenty-three cases seen, relatively early, without much involvement of the bladder wall, the results were unusually good.

122 South Michigan Avenue.

THE TREATMENT OF BLADDER CARCINOMA BY IRRADIATION AND DIATHERMY *

GEORGE GILBERT SMITH, M.D.
BOSTON

In discussing the treatment of bladder cancer by irradiation and diathermy, it has seemed fitting to include in the series of cases on which this paper is based those cases which were treated by excision of the tumor. By including the latter, there is given a possible standard for the comparison of results obtained by the different methods of treatment.

Table 1.—*Comparison of Results*

	Number of Cases Treated	Postoperative Deaths		Deaths from Recurrence		Free from Growth 2 Years After Operation	
		No.	Per Cent	No.	Per Cent	No.	Per Cent
By excision	11	3	27	2	16	3	27
By electrocoagulation	15	1	7	4	27	4	27
By radium	24	7	29	6	25	7	29
Total	50	11	22	12	24	14	28

Fifty cases, in all of which operation was performed within the last ten years, have been studied. In forty-seven, the diagnosis of carcinoma was made by microscopic examination of tissue removed. In two cases, the piece removed was too small or too necrotic for a satisfactory pathologic diagnosis. In both these cases, however, the tumor was of the infiltrating type and was obviously malignant. In another case, while the piece removed was reported to be a papilloma, other tumors were broad-based and necrotic, and were characteristically papillary carcinoma:

Of the fifty cases, eleven were treated by excision, fifteen by electrocoagulation and twenty-four by the implantation of radium. Nine cases in the last group were treated by electrocoagulation of the tumor before the implantation of radium, but as the hope of cure was based on the effect of the radium rather than on that of electrocoagulation, they are included among the cases of irradiation.

Comparison of the results of treatment in these fifty cases is almost impossible. No two tumors are alike, and a basis for comparing one with another is hard to find. From a survey of these cases it appears that they fell in a general way into three classes, and that each of the classes was treated by the method which seemed best adapted for handling it. Infiltrating tumors of the dome or lateral wall were excised whenever possible; scattered superficial carcinomas were treated by electrocoagulation. As many of the patients were

* Read before the Section on Urology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

operated on before it became customary for pathologists to indicate the grade of malignancy of the tumor, there is no basis for comparison from this point of view. Some of the most successful cases in each group have been rated as of high malignancy; it would appear from this limited evidence that the degree of malignancy is of no great prognostic value.

A comparison of the various methods of treatment may be made on the basis of operative mortality. It will be seen from table 1 that in this respect electrocoagulation is the safest method, as it has an operative mortality of but 7 per cent in contrast with one of 27 per cent for excision and one of 20 per cent for irradiation. Several factors enter into this. The cases selected for electrocoagulation usually showed a tumor of the superficial type, not obstructing the ureter. The patient was less liable to have pyelonephritis or to be profoundly toxic from absorption. Destruction of these superficial tumors causes less necrosis than that which necessarily attends destruction of infiltrating growths; when the latter are situated on the trigon, the absorption of toxins appears to be much greater, while the obstruction to ureteral drainage which results from edema about the ureteral orifice is almost certain to cause a pyelonephritis. Excision (table 2) entails a longer operation than either of the other methods, but, except in individuals whose circulatory system has little reserve, it seems to be well borne. One of my patients died of a failing heart and bronchopneumonia two months after operation; another died of cardiac failure four days after operation, and a third died of renal insufficiency six days after operation. In this case, one ureter was involved in the growth and was intentionally ligated.

Table 3.—*Results in Fifteen Cases Treated by Electrocoagulation*

Deaths due to operation:		
Four days after operation, from cardiac failure	1	
Deaths from recurrence:		
Death 5 months after operation	1	
Death 9 months after operation	1	
Death 1 year after operation	1	
Death 2½ years after operation	1	
Total	4	
Cases in which there were recurrences, which have been cleared up by intravesical electrocoagulation:		
(*a*) Cystoscopically well 14 months after operation	1	
Cystoscopically well 30 months after operation	1	
Cystoscopically well 48 months after operation	1	
(*b*) Symptomatically well 28 months after operation	1	
Total	4	
Cases without recurrence:		
19 months after operation	1	(by cystoscopy)
21 months after operation	1	(by cystoscopy)
36 months after operation	1	(symptomatically well)
Total	3	
Cases not traced	3	

The only postoperative death after electrocoagulation was due to cardiac failure (table 3). Of the seven deaths occurring after operation in the irradiated group, three were cardiac, two were due to renal infection, one was due to sepsis and one was due to general peritonitis following an unexplained perforation of the cecum.

Another basis for comparison of these methods is the matter of recurrence. In this respect excision shows the lowest percentage, the proportion of patients dying from recurrence after the use of this method being 18 per cent as against 27 per cent after electrocoagulation and 25 per cent after irradiation. Here again the figures must be analyzed carefully before they are accepted at their face value. The single, sessile growths which are suitable for excision are less likely to recur than are the papillary multiple growths which are usually selected for diathermic treatment. Excision of the latter, if it were possible, would probably be no more successful in preventing recurrences than is diathermy or radium. Many of the recurrences in the papillary group can be successfully treated through the cystoscope, provided the patient is seen often enough to catch them while they are still small and superficial.

In regard to the power of radium to destroy a cancer and to prevent recurrence, I admit I am still groping for light. My usual custom is to implant gold seeds of 1 millicurie each, 1 cm. apart, about the periphery *and through the center of the affected area. The dosage* varies from 1,320 to 3,800 millicurie hours. Apparently, the smaller doses were as effective as the larger. Of the six sessile cancers irradiated, four gave good results; one that was operated on nine years ago was a cancer of high malignancy (table 4). Another patient, with an epidermoid carcinoma grade 2, who was treated by electrocoagulation and then given 3,800 millicurie hours of radiation by means of gold seeds, died five weeks after operation from endocarditis. Autopsy showed the carcinoma still present about the site of the original tumor. The only interpretation which I can put on these observations is that cancers vary in their susceptibility to the action of radium. Whether this radiosensitiveness varies with the degree of malignancy cannot be deduced from this series. A high degree of malignancy does not contraindicate irradiation.

Table 4.—*Results in Twenty-Four Cases Treated by Implantation of Radium* *

Deaths due to operation:	
1 day after operation, from cardiac failure	1
6 days after operation, from cardiac failure	1
11 days after operation, from perforation of cecum and general peritonitis	1
(*a*) 3 weeks after operation, from left suppurative nephritis and cholelithiasis	1
(*b*) 4 weeks after	1
(*c*) 5 weeks after	1
Total	7
Deaths after recovery from operation:	
5 months after operation, from cancer	1
7 months after operation, from cancer	1
10 months after operation, from cancer	1
11 months after operation, from other causes	1
18 months after operation, from cancer	1
26 months after operation, from cancer	1
36 months after operation, from cancer	1
Total	7
Living and apparently well:	
16 months after operation (cystoscopy)	1
20 months after operation (cystoscopy)	1
2 years after operation (cystoscopy)	3
4 years after operation (cystoscopy) (Well clinically 7 years after operation)	1
5 years after operation (cystoscopy) (Cystoscopy in one of these; the other was reported well by L. M. D.)	2
6 years after operation (cystoscopy)	1
Total	9
Untraced (no record of death found)	1

* In nine of these cases the tumor was first electrocoagulated.

I am aware that the present trend in the use of radium is in favor of low, well screened doses applied over long periods. Even if this form of application does not increase the beneficial effects of radium, it is probable that it will reduce the tendency to employ the excessively large doses which many physicians have used in the past. The chronicity of a radium ulcer in any living tissue is remarkable, and in the bladder the macerating effect of the urine enables infecting bacteria to penetrate the slough and to keep up a cystitis of the most painful kind. Electrocoagulation is free from this fault, for the slough which it causes is thrown off in from four to six weeks, and a clean, well healed mucosa takes its place.

TABLE 5.—*Cases Treated With Radium*

Case	Age	Location	Pathologic Report	Type of Tumor	Radiation	Results
1	54	Trigon and left wall	Epidermoid cancer grade 2	Sessile, 4 cm. in diameter	*16 gold seeds 1.8 mc. each (3,860 mc. hours)	Death 5 weeks after operation from acute endocarditis; autopsy, considerable cancer present about site
2	73	Anterior wall down to trigon	Papillary cancer	Extensive superficial	11 glass seeds 1 mc. each put in trigon	No recurrence seen 16 months after operation; not traced after that
7	65	Trigon	Cancer, rapidly growing	Infiltrating	*13 gold seeds totaling 18 mc. (2,376 mc. hours)	Death 1 month after operation; pyelonephritis; no autopsy
8	70	Trigon	Papillary cancer, rapidly growing	Infiltrating	(1) 15 glass seeds 1 mc. each; (2) 4 steel needles 210 mc. × 8° totaling 3,680 mc. hours	Steady growth of tumor; death 10 months after operation
11	56	Trigon	Rapidly growing cancer	Infiltrating	*2 steel needles 20 + 33 mc. each for 10 hours = 530 mc. hours	Death 2 months after operation from sepsis and bronchopneumonia; no autopsy; rectovesical fistula
12	47	Trigon	Carcinoma, probably colloid	Necrotic, solid 4 cm. diameter, not pedunculated	*12 gold seeds 2 mc. each (3,168 mc. hours)	Nephrectomy necessary; no recurrence 20 months after operation; bladder healed 7 months after operation
13	70	Base and lateral walls	Cancer, rapidly growing	Small growths, slightly infiltrating	7 glass seeds 1 mc. each (924 mc. hours)	Recurrence, beginning 6 months after operation; later invaded perivesical tissues; death about 3 years after operation
14	58	Right ureteral area	Squamous cell cancer	Sessile growth, 3 × 1 cm.	10 glass seeds 1 mc. each (1,320 mc. hours)	Well by cystoscopy 4 years later; well clinically 7 years later
19	51	Base and bladder neck	Carcinoma, little differentiation	Sessile growth	*188 mc. in 4 steel needles for 3 hours; total = (564 mc. hours)	Death 7 months after operation
20	68	Left lateral wall	Papillary carcinoma	Superficial growth	*6 gold seeds 1.3 mc. each (1,030 mc. hours)	No recurrence 2 years after operation
21	60	Trigon, post urethram	Papilloma, a few mitotic figures	Scattered, superficial	14 glass seeds 1 mc. each (1,848 mc. hours)	Letter 5 years later says patient is well
23	52	Trigon	Epidermoid cancer	Infiltrating	10 gold seeds 1.7 mc. each; steel needles 152 mc. × 3° (2,700 mc. hours)	Death 5 months later
26	80	Bladder neck	Papillary carcinoma	Superficial	10 gold seeds 1 mc. each (1,320 mc. hours)	Death 1 day after operation of cardiac failure; no autopsy
28	75	Right ureteral area; root	Papillary carcinoma	Superficial	*9 gold seeds 1 mc. each (1,088 mc. hours)	Death 6 days after operation of cardiac failure; no autopsy
29	62	Left ureteral area	Papillary carcinoma	Superficial	*10 gold seeds 1.9 mc. each (2,400 mc. hours)	No evidence of recurrence 2 years after operation; bladder very irritable and still bleeds easily
30	50	Left lateral wall; right base	Papillary carcinoma	Superficial	*12 gold seeds 1.7 mc. each (2,692 mc. hours)	No recurrence; bladder clean 2 years later; control is poor
40	56	Trigon	Carcinoma	Tumor 3 cm. in diameter	10 glass seeds 1 mc. each (1,320 mc. hours)	Letter 6 years later says patient is well
41	55	Right lateral wall	Carcinoma	Papillary tumor 1 cm. in diameter	6 glass seeds 2 mc. each about periphery (1,584 mc. hours)	Death 11 days later from perforation of cecum, cause unknown; bladder showed no cancer
42	82	Left lateral wall	Carcinoma	Pedunculated tumor	12 glass seeds 1 mc. each (1,584 mc. hours)	Slough still present 9 months later; died 11 months after operation from other causes
43	62	Left lateral wall	No diagnosis; too necrotic	Sessile 1.5 cm. in diameter	10 glass seeds 1 mc. each (1,320 mc. hours)	Not traced; no record of death 7 years later
44	55	Right ureteral area	Carcinoma	Sessile 3 × 2 cm.	14 glass seeds 1 mc each; 4 needles 12.5 each for 20° (2,848 mc. hours)	Death 18 months later from cancer of bladder (possibly radium reaction)
45	65	Left lateral wall	Carcinoma	Superficial	10 glass seeds 1 mc. each (1,320 mc. hours)	Death 26 months later from cancer of bladder
46	70	Left lateral wall	Carcinoma	Infiltrating	15 glass seeds 1 mc. each; 4 needles 12.5 mc. each for ? hours (1,980+ mc. hours)	Death 3 weeks after operation; left suppurative nephritis; pericholecystitis and cholelithiasis; bladder cancer present
47	43	Right lateral wall	Squamous cell cancer of high malignancy	Sessile tumor 3 cm. diameter	11 glass seeds totaling 27 mc. (3,564 mc. hours)	Cyst 5 years later; no recurrence

* Diathermy used to destroy growth.

A comparison of the results based on the condition of the patient several years after operation shows that the percentage of successful cases is almost exactly the same, 27, 27 and 29, respectively, in all groups. Of the eleven cases of excision, three are free from recurrence after five years, one after one year; in one case there was a small recurrence seven months after operation. One was not traced. In the fifteen cases treated by electrocoagulation, there were four recurrences which were destroyed through the cystoscope. Cystoscopy in three of these cases showed the bladder to be free from growth fourteen months, thirty months and forty-eight months after operation. The fourth patient was reported as symptomatically well twenty-eight months after operation. The type of tumor usually treated by electrocoagulation, i. e., the superficial papillary type, has seemed to be more likely to recur after a considerable period than is the infiltrating but more localized type that was usually excised or irradiated. Two cases were proved by cystoscopy to have no recurrence nineteen and twenty-one months after operation; a third patient was symptomatically well thirty-six months after operation. Three were not traced.

Following irradiation, a cystoscopically negative bladder was found: sixteen months after operation in one; twenty months after operation in one; two years after operation in three; four years after operation in one (this patient was reported symptomatically well seven years after operation), and five years after operation in one. One patient was reported well by his own physician five years after operation and another one six years after operation. One was not traced, but no record of death was found seven years after operation.

SUMMARY

Cases of bladder carcinoma fall into two groups, the deeply infiltrating and the superficial papillary. Those in the first group, if they have not metastasized or extended beyond the bladder wall, may be excised or may be destroyed with radium with about a 25 per cent chance of a cure. If the growth is situated on the trigon or about a ureter, the chances of success are much less than if it is situated in the dome or lateral wall. For these deeply infiltrating growths, diathermy has not seemed particularly suitable; I have preferred the other methods.

Table 6.—*Cases Treated by Excision*

Case	Age	Location	Pathologic Report	Results
3	57	Dome	"Essentially malignant" papillary tumor	No recurrence in 5 years
6	62	Right lateral wall	Carcinoma, very little differentiation	No recurrence in 5 years
9	67	Anterior wall and roof	Rapidly growing cancer	Total cystectomy; death 14 months later from recurrence
10	63	Base above trigon	Epidermoid carcinoma; papillary type	Not traced
15	47	Generalized	Carcinoma	Total cystectomy; death from metastasis 8 months after operation
27	75	Right lateral wall and ureter	Epidermoid carcinoma grade 3	Died 6 days after operation of renal insufficiency (right ureter tied)
32	48	Left lateral wall and bladder neck	Carcinoma, rapidly growing	Left ureter transplanted; nephrectomy later; no recurrence in 3½ years
33	74	Dome	Carcinoma	Died 2 months after operation of bronchopneumonia
35	45	Dome	Squamous cell carcinoma	No recurrence in 1 year
49	67	Left lateral wall and trigon	Rapidly growing cancer	Death 4 days after operation; cardiac failure or embolus
50	64	Left ureter	Squamous cell carcinoma, papillary type	Small recurrence 7 months after operation

Cases of the second group, with tumors of the superficial, papillary type, are best treated by electrocoagulation. If the bases of the tumors are indurated, they may be irradiated by the implanting of one or two gold or platinum seeds. While the immediate mortality in this group is low, 7 per cent, the later mortality from recurrence is slightly higher than in the group treated by excision or irradiation. These cases should be watched with special care, for small recurrences are likely to spring up in any part of the bladder. Cystoscopic examination should be done at least every three months during the first year, and at least every six months for five years thereafter.

CONCLUSIONS

1. This study is based on fifty cases of carcinoma of the bladder, of which eleven were treated by excision, fifteen by electrocoagulation and twenty-four by irradiation.

Table 7.—*Cases Treated by Diathermy*

Case	Age	Location	Pathologic Report	Prognosis	Results
4	52	Trigon	Epidermoid carcinoma grade II	Extensive; hopeless	Death in 5 months
5	64	Close to right ureter	Papillary cancer rapidly growing; base not involved	4 cm. in diameter, pedunculated; good	Bladder healed 10 weeks after operation; no record of death 5 years later
16	56	Right side of trigon	Carcinoma	Fair	No recurrence after 1½ years; 2½ years after operation recurrence elsewhere in bladder; death
17	50	Left base close to ureter	Papillary carcinoma	Pedunculated growth 6 cm. diameter; good	No recurrence 19 months after operation
18	63	Dome and ureteral orifice	Papillary carcinoma	Two solid pedunculated growths on roof; fair	Recurrence in 10 months; sessile, infiltrating; undoubtedly died from recurrence
22	66	Trigon	Epidermoid carcinoma	Superficial scattered; fair	13 months later, recurrence on posterior edge of urethral orifice; destroyed through cystoscope; symptomatically well 13 months later
24	50	Trigon	Epidermoid carcinoma; papillary type	Extensive but superficial; fair	1 year after operation several small papillary recurrences, destroyed through cystoscope; bladder all right 2 months later
25	53	Right ureter, base and bladder neck	Papilloma; a few mitotic figures	One solid, pedunculated tumor, several buds; good	No recurrence 21 months after operation
31	60	Generalized	Papillary carcinoma	Many pedunculated tumors; fair	Recurrences (5 or 6 solid, pedunculated growths) 14 months after operation; destroyed through the cystoscope; bladder clean 2½ years after operation
34	60	Right base	Papillary carcinoma	Pedunculated tumor 2 cm. in diameter; good	Recurrence in treated area 5 months after operation; death from metastases 9 months after operation
36	40	Trigon	Papillary carcinoma, low malignancy	....	Not traced
37	72	Right ureteral region	Fragment too small for diagnosis; clinical malignancy	Appeared to invade wall; fair	Clinically well 3 years after operation; cystoscopy not done
38	52	Trigon and right lateral wall	Carcinoma, invading muscle	Fair	Not traced
39	80	Left ureteral region	Carcinoma	Good	Death 4 days after operation from cardiac failure; at autopsy, no cancer found
48	48	All over bladder	Papilloma; no mitotic figures seen (some of tumors necrotic)	Generalized, superficial; fair	A few small recurrences; bladder free from growth 4 years after operation

2. Operative mortality was lowest in the cases treated by diathermy, but deaths from recurrences were slightly greater in this group.

3. No one method is suitable for all cases. Deeply infiltrating carcinomas are best treated by excision or irradiation, depending on their location. Superficial papillary growths should be destroyed by electrocoagulation, and the bases, if indurated, should be irradiated.

4. With all of these methods, successful results were obtained in one out of every four (25 per cent).

THE RADIUM TREATMENT OF CANCER OF THE BLADDER [*]

B. S. BARRINGER, M.D.
NEW YORK

The treatment of tumors of the bladder is still in a state of evolution. Surgery, diathermy and radium have been and still continue to be contestants for honors. The surgical removal necessitates no especial surgical equipment other than that found in every well appointed hospital. The radium treatment of malignant diseases is becoming more and more a problem that can best be dealt with in specially equipped hospitals. Radium itself is expensive and its proper use implies a certain amount of special training.

A comparison between the results with the use of radium and surgery can be made only when some common ground of classification can be reached. The greatest single advance in this direction is the grading by Broders of tumors into various classes of malignancy. I have for some time been so grading bladder tumors and have to date graded sixty-two tumors (reported elsewhere). My earlier cases were not graded. I have been unwilling to discard these cases and therefore, perhaps for the last time, have classified my cases under papillary and infiltrating cancers.

Table 1.—*Ninety-Eight Cases of Cancer of the Bladder Diagnosed on Pathologic Observations*

If we who use radium could be in the position of the surgeon and could have the entire tumor for pathologic examination, our statistical problem would be easier. As a routine we attempt to get different portions of a tumor and particularly a portion of its base for examination. We have perhaps been too loath to dig deeply into the base of a tumor to get a specimen. We have thought that dissemination of tumor cells might result. So we have believed that the clinical diagnosis should have the last say. If a tumor was sloughy, that was classified as a carcinoma, even if the diagnosis came back papilloma. If a diagnosis was returned papillary carcinoma and an indurated base was felt at the time of open operation, or if radium-bearing needles when inserted into the tumor base met resistance and felt as though they were going through gristle, it was felt that the diagnosis of infiltrating carcinoma was justified. The statistical results go far toward proving this. There are some, however, who disagree with this point of view. For this reason I have given two tables in which radium end-results may be studied; table 1, in which the diagnosis has been made pathologically, and table 2, in which the pathologic diagnosis has been modified by the clinical diagnosis.

Table 2.—*One Hundred and Twenty-Seven Cases in Which Weight of Diagnosis was Clinical Rather Than Pathologic*

* Papillomas with atypical cells are grouped under this heading.
† In nearly all these cases the pathologic diagnosis was papillary cancer.

In table 1 I have presented the end-results of ninety-eight cases of cancer of the bladder[1] with the diagnosis based solely on the pathologic observations.

In 127 cases of carcinoma of the bladder, the weight of diagnosis is given to the clinical rather than to the pathologic side[2] (table 2).

A comparison of these two tables shows 98 cases pathologically diagnosed and 127 cases in which the clinical diagnosis was given more weight than the pathologic.

The discrepancy between the numbers, twenty-nine cases, is that in which no pathologic diagnosis was made. In a number of these a sloughy part of a tumor which was removed showed no tumor under the microscope. A few were diagnosed by their failure to react to fulguration. In the largest part no specimen large enough for pathologic examination was obtained, but the diagnosis of carcinoma was made because the tumor was sloughy.

---

[*] From the Urological Service, Memorial Hospital.

[*] Read before the Section on Urology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

[1] I have reported only papillary and infiltrating cancers. Papillomas with atypical cells have been classified as papillary carcinomas. Tumors classified as papillomas have been excluded.

[2] In a good many of these cases the pathologic diagnosis was made from the papillary projecting portions of the tumors which were removed. Many of these tumors had started as papillary cancers and in the course of their growth invaded and infiltrated the bladder wall. In other words, they should have been classified as infiltrating cancers.

In the first table 43 per cent of the papillary carcinomas were controlled three years. Table 2 shows 55 per cent controlled three years. This discrepancy is undoubtedly caused by the inclusion in the second table of a number of borderline cases which lie between papilloma and papillary carcinoma.

There is no great difference in the three year controlled cases of infiltrating carcinoma, 29 per cent and 27 per cent, although it is interesting to note that those pathologically diagnosed give slightly better results.

The histories of the two cases of infiltrating cancer grade 3 in both of which the disease was controlled for nine years, is as follows:

CASE 1.—A man came to the hospital, Dec. 19, 1920, because of dysuria and urinary frequency followed by hematuria of three months' duration. Cystoscopy showed a necrotic tumor of the anterior bladder wall extending from the internal urethral orifice. Cystotomy was done, December 20. A flat, ulcerating tumor 4 by 3 cm. was found. This was implanted with twenty-one glass radium seeds, totaling 1,709 millicurie hours. Screened radium totaling 430 millicurie hours was packed against the tumor. The patient subsequently had much sloughing of the tumor with calcareous deposits. Dec. 21, 1922, a cystotomy was done to remove much soft calcareous material. No tumor was present. He recovered and was well, Feb. 6, 1930. The pathologic examination of the original tumor showed squamous infiltrating carcinoma, grade 3.

CASE 2.—A man, aged 33, who came to the hospital, May 13, 1920, had had slight dysuria two years before, then polyuria and, four months before, hematuria. Cystoscopy showed a flat ulcerating tumor of the right upper bladder wall. A cystotomy was done the day of admission. A tumor 2.5 by 2.5 cm. was found. A specimen was taken, and it was implanted with fifteen glass seeds of 0.3 mc. each totalling 594 mc. hours. He recovered. Oct. 21, 1920, he had a slight recurrence at the edge of the original tumor. This was implanted with glass seeds through the cystoscope. On many subsequent cystoscopies his bladder has been clean. He was well, Nov. 20, 1929. The pathologic examination of the original tumor showed infiltrating carcinoma, grade 3.

A comparison between the results of the implantation of radium and the operative removal of cancer of the bladder is difficult because surgery selects the cases that are operable and discards the rest.

At the Memorial Hospital irradiation has been given every patient with cancer of the bladder in whom the cancer was believed to be confined to the bladder, no matter how large the tumor was. Therefore, in this series are included many inoperable cases. In a fair percentage of cases the tumor occupied one third or more of the bladder. In these cases 28 per cent were tumors whose bases were 6 sq. cm. or less. In 72 per cent the bases were greater than 6 sq. cm.

In 127 tumors 81, or 63 per cent, touched or were adjacent to the trigon. Many of the patients would have required total cystectomy if operative removal had been contemplated. In nineteen, or 15 per cent, the location was on the base posterior to the trigon. In eighteen, or 14 per cent, the tumor was on the lateral walls and easily removable. In one, or 0.7 per cent, it was on the apex. In eight the site was not determined.

In the 63 per cent of tumors touching the trigon the operative mortality following the surgical removal of these tumors, if that had been possible, would have been between 10 and 20 per cent, and a fair number of these tumors could not have been removed surgically.

DIFFERENT FORMS OF RADIATION

Physicians have been able from the very start (1914) to control a good percentage of malignant tumors of the bladder with radium. They first used screened radium applied in a somewhat hit or miss manner; then partly screened and partly unscreened radiation (glass seeds) more accurately applied, but with much caustic beta radiation; finally, they used accurately applied gold seeds giving off no beta radiation.

Beta radiation certainly causes sloughy areas of the bladder, which only too often become covered with troublesome phosphatic deposits. On the other hand, some of the most malignant tumors I have ever cured were controlled solely by glass seeds.

It is an open question at present whether or not this caustic action of beta radiation is a factor in controlling cancer of the bladder.

The size of the dose of radium is an important factor. The reason many who use radium fail is that a very small dose is used. I have analyzed a good many such cases and have found almost without exception this to be the reason for failure.

One gold seed of 2 mc. to 1 sq. cm. of tumor should be used. I have put as many as forty such seeds in a single very large tumor. Considerable bladder irritability and some rectal irritation may follow this dosage (the latter if the seeds are near the rectum). The so-called radium burns may follow this administration.

I have always worried more about the malignant nature of a tumor of the bladder than about a radium burn. It has been calculated that between ten and fifteen erythema doses are necessary to control the radioresistant tumors. This accounts for the reason why high voltage roentgen therapy so often fails. It is difficult to get into the tumor by this method more than one and one-half erythema doses.

THE SUPRAPUBIC OPERATION

Finally, let me stress the decided difference between the operative mortality when a tumor is removed by surgery and when it is implanted by radium by the suprapubic route. In 109 consecutive personal cases of the suprapubic implantation of radium, 4 patients died in the hospital, an operative mortality of 3.6 per cent. One died of shock and hemorrhage, notwithstanding two blood transfusions; one of diabetic coma; one of uremia, and one of shock (a poor heart and old age contributed). A considerable number of these cases would have been classed as inoperable. Operative removal in the cases of this series which were operable would have been between 10 and 20 per cent.

In doing the suprapubic implantation, spinal anesthesia has been used. The bladder should not be mobilized. The abdominal wound should be thoroughly screened with gauze before the bladder is opened. Great care should be taken not to spill the bladder contents over the wound; a good exposure of the tumor is necessary; the Cameron light should be used for retraction and to illuminate the bladder; open wire retractors devised at the Memorial Hospital are useful for a good exposure of the tumor; the papillary portion of a tumor should be removed by some form of cautery; the radium implantation should be accurate; a small suprapubic drainage tube (from 18 to 22 F.) should be left in place for about a week or longer if the bladder is dirty or the radium dose is very large; the bladder is not sutured to the abdominal wall.

CONCLUSIONS

1. Tumors of the bladder should be classified according to their relative malignancy (Broders' method). In this way a comparison of results can be made.

2. The papilloma with atypical cells should be regarded as a malignant tumor and so treated.

3. If only the projecting part of a tumor is removed for pathologic examination, the clinical estimate of a tumor's malignancy should receive more weight than the pathologic.

4. In 127 cases, the results of radium implantation were: Of forty-five cases of papillary carcinoma, twenty-five cases, or 55.5 per cent, were controlled more than three years. Of eighty-two cases of infiltrating carcinoma, twenty-three cases, or *27.5 per cent,* were controlled more than three years.

5. The suprapubic implantation by radium has an operative mortality of between 3 and 4 per cent, while the operative removal has a mortality of between 10 and 20 per cent.

When one considers that all tumors of the bladder excepting those which had extended beyond the bladder were irradiated and included in these statistics, one gets a fairly *comprehensive idea of the decided superiority* of radium removal to operative removal.

THE PATHOLOGY OF MALIGNANT BLADDER NEOPLASMS

WITH ESPECIAL REFERENCE TO THE GRADING OF EPITHELIOMAS *

HAROLD D. CAYLOR, M.D.
BLUFFTON, IND.

Since approximately 95 per cent of the malignant vesical lesions are epitheliomas,[1] any general consideration of the pathology of tumors of the bladder must include a study of epitheliomas and their associated papillomas.

There has been a divergence of opinion [2] regarding the relative benignancy and malignancy of the so-called papillomas of the bladder. One group [3] has maintained that these tumors were benign and the other [4] has stated that they were malignant. Certain characteristics of the primary growth, its gross and microscopic appearances and its subsequent actions deserve consideration as criteria in deciding the question as to the classification into which a neoplasm belongs.

As one approaches the dividing line between malignant and benign lesions, the differentiation between them frequently becomes increasingly difficult and, as every physician knows, certain neoplasms try his mental acumen to the limit to place them properly as malignant or as innocent tumors. In the final analysis the malignancy and benignancy of neoplasms are only relative terms and the merging of one group into the other may be almost imperceptible.

Some papillomas of the bladder may implant themselves in other parts of the organ, or in a suprapubic wound following an open operation, or they may recur locally.[5] Less commonly, papillomas of the bladder may show infiltration of the wall; the so-called infiltrating papilloma of the bladder. All these characteristics are features that may also be present in epitheliomas of the bladder.

Analysis of the microscopic appearance of the so-called papillomas of the bladder reveals usually a *frondlike growth of the epithelium of the bladder* with a vascular stroma forming the central portion of the stalk.

The epithelial cells composing the neoplasm are round or oval and usually tend to arrange themselves at right angles to the vascular stalk. These epithelial cells do not show mitotic figures, although irregularity of size of the nucleus is not uncommon. In my opinion, in agreement with Broders and others,[6] papillomas bear the same relationship to the bladder epitheliomas as grade 1 squamous cell epitheliomas of the lip, for example, bear to the more malignant grades of squamous cell epitheliomas of this organ.[7] On this account I feel that these bladder neoplasms should not be considered and treated as benign papillomas but as epitheliomas of a low degree of malignancy. These neoplasms have the characteristics of low grade epitheliomas; that is, they recur if incompletely removed, they rarely metastasize to adjacent lymph nodes, their growth is by direct extension, invasion or implantation and, finally, their cells have the characteristics of low grade epithelioma cells.

Broders,[7] in 1920, published his first paper on the grading of cancer, and at intervals since this time he has elaborated on his scheme and applied it to epitheliomas and carcinomas of different organs.[8] His *study of the urogenital epitheliomas was published* in 1922.[2] The basic principle of grading cancer according to this scheme of Broders is a consideration of the amount of differentiation which the cancer cells manifest.

Differentiation is the property which cells of a neoplasm possess which enable them to develop characters revealed by normal adult cells of the tissue from which the new growth arose. For example, a squamous cell epithelioma may, when it is *well differentiated,* reveal keratinization such as is seen in the normal skin. The cells of an epithelioma of the urinary bladder may reveal a microscopic appearance much like the cells of the normal bladder epithelium. This property of cells *to differentiate enables them to* "put the brakes on their growth," as Broders [8] has said. Cells that are undifferentiated, on the other hand, are rapidly growing and hyperchromatic with irregularly stained and frequently *prominent nuclei. Mitotic figures may be abundant* in this group of rapidly growing cells. Cancer cells may be so undifferentiated that they may have lost almost all the elements which identify them as related to any particular organ or tissue, as MacCarty [9] noted years ago.

In order to give his scheme of classification practical application, Broders divided his grading into four groups, designated grade 1, 2, 3 and 4. Tumors in grade 1 were the least malignant while those in grade 4 were the most malignant. Broders considered those epitheliomas which revealed from almost complete differentiation of the cells to differentiation in about 75 per cent of the cells as grade 1. Those tumors showing differentiation in from approximately 75 per cent of the cells to 50 per cent of the cells were considered as grade 2. The range of differentiation in grade 3 epitheliomas was from 50 per cent to 25 per cent, and in the grade 4 group the range of differentiation was from 25 per cent to practically no differentiation. The number of mitotic figures and the number of cells with large deeply stained nuclei play an important rôle in properly placing an epithelioma of the bladder in a certain grade. Keratinization, which is so commonly a guide in the grading of squamous cell epitheliomas of the lip, for example, is uncommonly seen in epitheliomas of the bladder and is consequently not a great aid in grading these tumors.

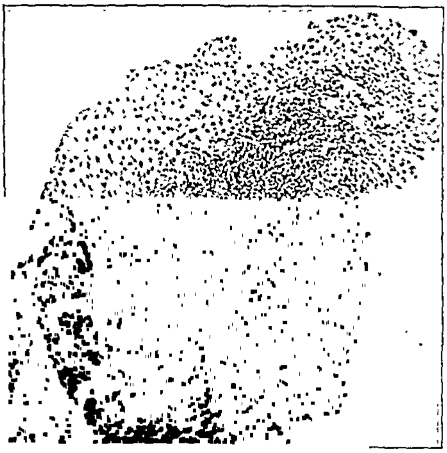

Fig. 1.—Grade 1 epithelioma: The epithelial cells covering the left side of the frond are well differentiated and apparently contain keratin, while those along the right border are less differentiated and reveal more irregularity of form, size and staining reactions; × 66.

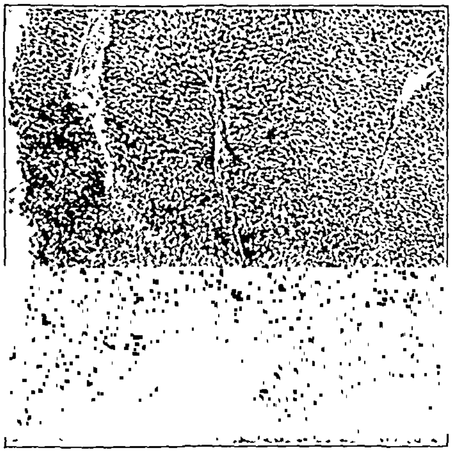

Fig. 2.—Grade 1 epithelioma, illustrating the usual features of this type of tumor, namely, round or oval, regular well differentiated cells; × 66.

Regarding tumors of the bladder, Broders[2] has said:

> A neoplasm can accomplish only what its cells can accomplish; if its cells are active, it is active. A neoplasm may be of papillary form and of a low degree of malignancy, or it may be papillary and of a high degree of malignancy. It may be flat or ulcerated and of a high degree of malignancy, or it may be flat or ulcerated and of a low degree of malignancy.

Hunt has noted an apparent tendency for the development of highly malignant epitheliomas of the bladder in the base of that organ, as opposed to the lateral wall or dome. In a series of 150 epitheliomas of the base, 64.6 per cent were grade 3 and 4 as opposed to 53.6 per cent of 214 epitheliomas of the lateral wall and dome. Hunt has furthermore found in a series of 480 graded epitheliomas of the bladder that 10 per cent were grade 1, 32 per cent grade 2, 35 per cent grade 3, and 23 per cent grade 4; 58 per cent were grades 3 and 4. In a series of 370 graded epitheliomas of the bladder irrespective of the size of the lesion, its situation or the magnitude of the operation, Hunt found that 65 per cent of the patients on whom a radical operation had been performed and in whom the lesions were graded 1 and 2 lived three or more years without a recurrence, in contrast to 35 per cent of the patients whose lesions were graded 3 and 4.

FOUR GRADES OF EPITHELIOMAS

Grade 1. These epitheliomas are most common in the lateral walls or dome of the bladder, although they may occur in any location.

Grossly they usually appear as soft papillary lesions, although there are exceptions. Small areas of ulceration may be present on their surface and incrustations of urinary salts are occasionally visible and palpable. When these tumors are present for a long time in the bladder, they may present a bulk that includes a good share of the bladder lumen. Multiple tumors are not uncommon.

The grade 1 epitheliomas reveal differentiation in approximately three fourths of their cells and undifferentiation in not more than one fourth of their cells.

In their microscopic appearance they are usually characterized by round or oval well differentiated epithelial cells several layers thick arranged at right angles to a vascular stalk, which usually makes up the center of the tumor. Keratinization is occasionally present in the epithelial cells (fig. 1). There are slight variations from the typical form but in general the grade 1 epitheliomas of the bladder conform fairly closely to this type (fig. 2).

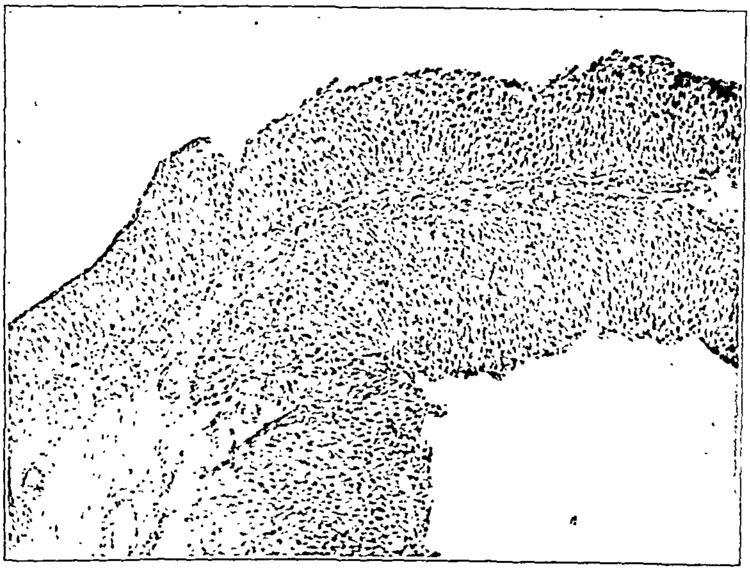

Fig. 3.—Grade 2 epithelioma: The cells composing this tumor are less differentiated than those in the grade 1 group, as their irregularity in size and staining reaction indicates; × 100.

Grade 2. This group of epitheliomas is commonly papillary and has a predilection for the lateral walls and dome of the vesica. Depending on their age and rate of growth, these tumors may form a large bulk of tissue, which may fill a portion of the bladder lumen.

The deeper structures of the bladder wall are usually not involved early in this disease by the neoplasm. Ulceration and incrustation may be present on the surface of the tumor.

The microscopic appearance of this tumor group, like that of grade 1, reveals a frondlike growth of epithelial cells with a vascular stroma or stalk. The differentiated cells compose from three fourths to one half of the tumors and the undifferentiated cells compose from one fourth to one half of the neoplasms. Since the epithelial cells are less differentiated, they present more variation in their size and nuclear staining qualities. Mitotic figures may occasionally be seen. There is sometimes an increase of the epithelial cellular elements and an apparent decrease of the stroma or stalk of the frond as compared to grade 1 epitheliomas, although this change is not of great importance (figs. 3 and 4).

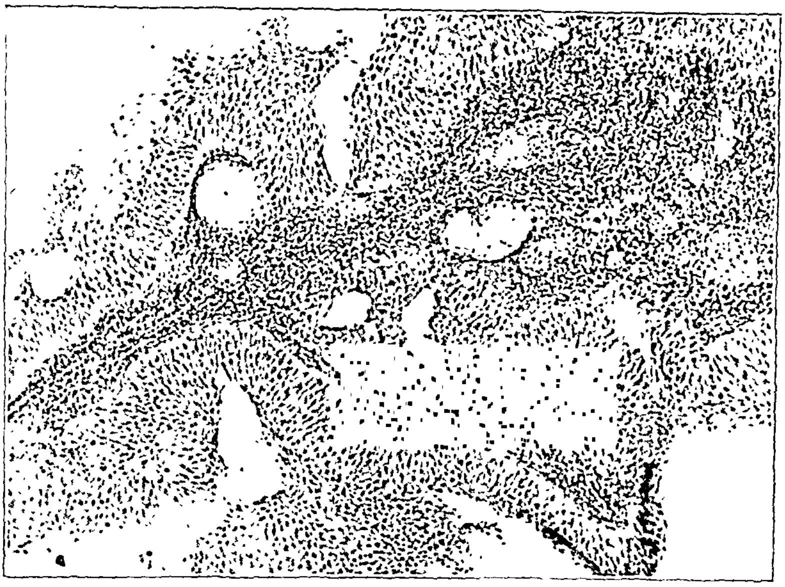

Fig. 4.—Grade 2 epithelioma, × 100, to be compared with figures 1 and 2.

Grade 3. Grossly, this group of epitheliomas is usually characterized by a flat infiltrating type of growth that may or may not show ulceration and necrosis. The base of the bladder is the most common location for this group of tumors.

The cells that make up the tumor are usually large hyperchromatic units, which frequently exhibit mitotic figures and a decreasing amount of differentiation. The differentiated cells compose from one half to one fourth of the new growth and the undifferentiated cells range from one half to three fourths of the tumor (fig. 5). If the tumor has a papillary character it usually is composed chiefly of epithelial cells in comparison to the amount of stroma so commonly seen in the epitheliomas of the bladder that are in the lesser degrees of malignancy (fig. 6). The infiltrating portions of the tumor frequently burrow deeply into the muscular coat of the bladder and perivesical tissues and lymphatics.

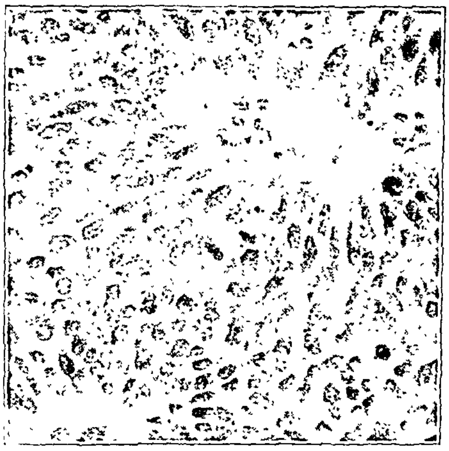

Fig. 5.—Grade 3 epithelioma: Near the center of this section a mitotic figure is visible; the cells composing this tumor are large, hyperchromatic and apparently rapidly growing and not greatly differentiated; × 300.

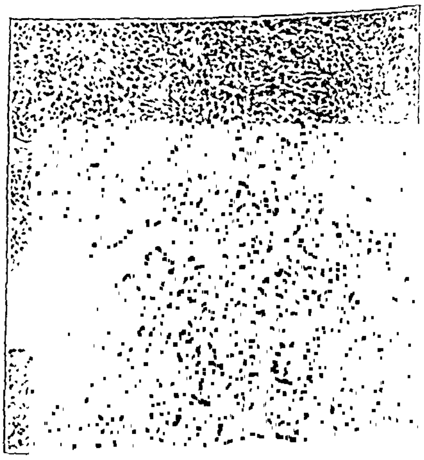

Fig. 6.—Grade 3 epithelioma: This neoplasm illustrates the increase of the epithelial elements over the stroma in the higher grades of malignancy; × 66.

Grade 4. These tumors, like those of the preceding group, are usually flat lesions which may or may not ulcerate. The most common gross character of these lesions is their marked invasive tendency illustrated in figure 7.

The cells making up their group are large, highly malignant cells usually with mitotic figures in abundance. Cell differentiation ranges from one fourth of the cells to practically none of the cells. The undifferentiated cells compose from three fourths of the tumor to almost the entire neoplasm. The stroma in the tumor itself is usually in little evidence. In the invading portions of the tumor, small islands of malignant cells may be found scattered among muscle and fibrous connective tissue bundles (figs. 7 and 8). Lymph vessels are many times invaded early and thus the extensive metastasis and the large number of inoperable tumors found in this group are accounted for.

IMPORTANCE OF BIOPSY OF BLADDER TUMORS

The removal of a specimen from tumors of the bladder for diagnosis has gained a new significance with the establishment of the virtue of the grading of epitheliomas of the bladder. A rational plan of treatment can be devised and executed as indicated by the grade of malignancy of a tumor, its location and extent, by means of the microscopic examination of a small specimen removed from a neoplasm of the bladder through a cystoscope. The objections which have been raised to the removal of a specimen of bladder lesions for diagnosis are many times based on a clinical opinion that the lesion was affected adversely by such a procedure; on the other hand, experimental evidence has accumulated in carefully controlled experiments which seem to indicate that biopsy had no influence on the rate of growth of cancer or on its metastasis in experimental animals.[10] Bumpus, in commenting on the removal of a specimen from a tumor of the bladder, said:

> Biopsy has not to my knowledge resulted in spreading the growth or producing metastasis, although such authorities as Thomas and Corbus warn against the practice. As parts of the neoplasm of the bladder break off from time to time as a result of the action of the musculature of the bladder, it is difficult to understand why the removal of pieces no larger than those frequently voided by the patient should result in a spread of the growth.

There are definite pitfalls into which the removal of specimens of tumors of the bladder may lead one. Most of these errors can be avoided with care and cooperation. The most troublesome experience is the failure to find malignant changes in a lesion which, from a clinical and cystoscopic standpoint, should be malignant. A single report of inflammatory tissue in such a case should not be considered as final. The urologist should remove another specimen, if necessary, in his efforts to "get the right piece," and the pathologist should leisurely study over and over again many sections from all the tissue removed. If multiple lesions are present in the bladder, specimens should be removed from each, for some of the lesions may be benign or inflammatory while others may be malignant.

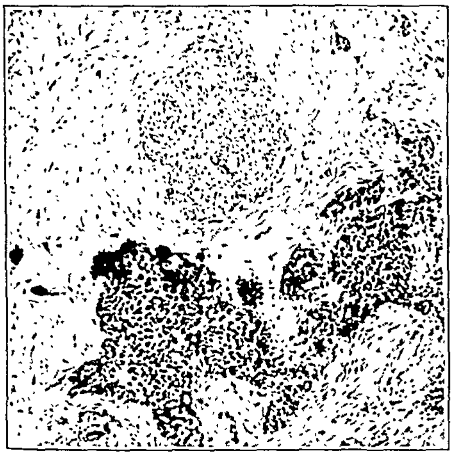

Fig. 7.—Grade 4 epithelioma cells invading the bladder wall; × 66.

Frater[11] recently found in studying a large number of bladder tumors that the grade of malignancy of a bladder tumor specimen removed cystoscopically could be relied on as an index of the grade of malignancy of the whole tumor because the malignancy of bladder epitheliomas did not vary greatly in different areas of the same tumor. That is, there was no important variation in the grade of malignancy between the surface and the base of the lesion. This observation is extremely valuable, particularly in regard to the worth of the removal of a specimen through a cystoscope as a diagnostic procedure. Frater furthermore found that epitheliomas of the bladder did not change, with few exceptions, in their grade of malignancy in specimens removed at different intervals from original tumors or their recurrences. The period over which these observations were made varied from a few months between different specimens to as long as approximately twelve and one-half years.

LESS COMMON BLADDER NEOPLASMS

An adenocarcinoma may develop in the urinary bladder. These cancers apparently develop from the von Brunn glands[5] and are composed of columnar cells usually arranged in acini with stroma surrounding them much as is seen in carcinoma of the prostate or breast. These bladder adenocarcinomas likewise lend themselves to the same grading as other cancers. The particular specimen illustrated happens to be a grade 2 adenocarcinoma. A knowledge of the possible development of these adenocarcinomas in the urinary bladder is of value because of the close resemblance of these neoplasms to prostatic carcinoma and the possibility of suspecting the prostate as the origin of the cancer rather than the urinary bladder.

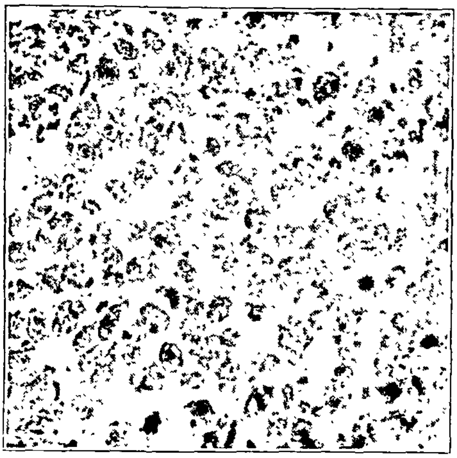

Fig. 8.—Grade 4 epithelioma: This tumor presents practically no differentiation of the cells; ×480.

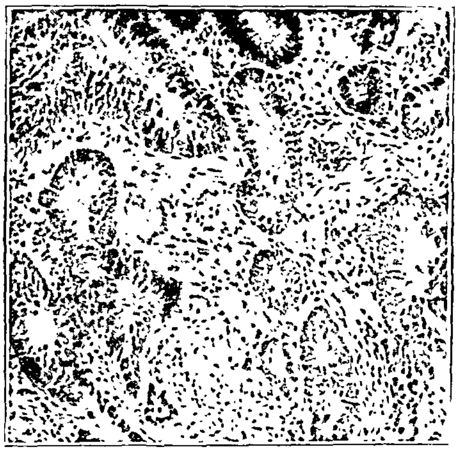

Fig. 9.—Adenocarcinoma, grade 2, rising in von Brunn's glands; × 100.

Sarcoma of the bladder reveals a few peculiar features that deserve especial mention. There is an unusual predilection of this neoplastic disease to occur most commonly between the ages of 51 and 60 years and 1 and 5 years.[12] This occurrence in the very young and so late in life is unusual. The points of origin of sarcoma of the bladder arranged according to the frequency of their occurrence are as follows: base, trigon, anterior bladder wall, lateral walls, vesical orifice, entire bladder, ureteral orifice, urachus and fundus. The types of bladder sarcoma that have been described include fibrosarcoma, lymphosarcoma, leiomyosarcoma and rhabdomyosarcoma, and they occur in about the order named.

SUMMARY

So-called papillomas of the urinary bladder should not be considered as benign lesions but as low grade papillary epitheliomas of the bladder, for they bear the same relationship to epitheliomas of the bladder as grade 1 squamous cell epitheliomas of the lip, for example, bear to the more malignant grades of epitheliomas in this organ. The grading of bladder epitheliomas, as devised by Broders, is described, illustrated and discussed. The importance of the removal of specimens from bladder epitheliomas as a diagnostic procedure is noted. The possibility of using diagnoses made from biopsy specimens as a basis for the development of a plan of treatment of bladder epitheliomas is emphasized and discussed. Some salient features of less common malignant lesions of the bladder are mentioned.

303 South Main Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. KRETSCHMER, SMITH, BARRINGER AND CAYLOR

Dr. H. G. Bugbee, New York: That no one method of treating carcinoma of the bladder is satisfactory for all cases is self-evident by the variety of methods and technics now in use. Probably the best effort that has been made to standardize the pathology of bladder tumors is that of Broders. Few, however, I believe, will go as far as to make this classification or gradation an absolute rule for the application of a certain technic of operation in each case. The amplification of Broders' classification has been ably presented by Dr. Caylor, and his illustrative cases are well chosen. The profession is willing to take the ground that all bladder tumors are potentially malignant. Even the so-called benign papilloma, as he states, will recur; it grows by direct extension, invasion, or implantation, and its cells have the characteristics of low grade epithelioma cells. This type of tumor responds readily to fulguration and can be kept under control if thoroughly removed and the bladder kept under regular observation. From a practical standpoint, tumors of the bladder can be divided into three groups—papilloma, papillary carcinoma and infiltrating carcinoma—with a definite and accepted line of treatment in the first group only. As to just how much the treatment is influenced by the knowledge that a tumor is of a higher grade of malignancy is questionable. The knowledge of the grade of malignancy of the individual growth will probably help in giving a prognosis. If a tumor of the bladder does not respond at once to fulguration, I believe that the bladder should be opened and studied under sight and feel. What seems to be a papilloma of the bladder may be the apex of an infiltrating carcinoma with a broad intramural base. With the bladder open, when a carcinoma is exposed, effort is directed toward the elimination of the growth, and the methods at one's disposal consist of radical excision, diathermy, cautery, radium implantation or a combination of these procedures, plus the possible postoperative use of high voltage roentgen therapy. I have used each of these methods and various combinations, and I still believe that the technic to be employed depends on the condition found in the individual case. If the growth is in a position that renders excision possible, I prefer to excise the growth and to treat any doubtful areas of invasion by implantations of radon; other growths, infiltrating the base of the bladder and trigon or large areas of the bladder wall, rendering excision impossible, by cautery with implantation of radon seeds in the base; while other flat, infiltrating growths, or multiple growths, with radon seeds only.

Dr. Budd C. Corbus, Chicago: Dr. Barringer is not going to change his method of using radium in the treatment of tumors of the bladder because he has used it all this time, and his results warrant his going on with this method. Others are not going to change their procedure of treating tumors of the bladder with diathermy because they believe in its efficacy. I think the mistake lies in confusing the different methods. A physician should stick to one method, master the technic and hold on to it. When first one method is used and then another, one does not know which is responsible for the result, whether satisfactory or not. Ten years ago, or perhaps longer, we were asked to "stick to our last" and we are glad to do this. I was pleased to hear Dr. Kretschmer's paper, citing his favorable results in the treatment of tumor of the bladder. I also was glad to hear the paper on the classification of tumors of the bladder by Dr. Caylor. I think the point to appreciate in his paper is that the proper procedure is to destroy the growth at the first attack if possible. I believe that the term "electrocoagulation" should be used rather than fulguration. Fulguration means sparking and does not destroy the growth. The one important thing, whatever technic is used, is that one must be careful not to transplant tumor cells in removing the growth. The use of retractors, the tearing of tissue which leaves raw or cut surfaces where cancer cells can get in and find a foothold, must be avoided. I think great credit is due Dr. Beer in working out a careful technic in the removal of tumors of the bladder. His method of flooding the field with alcohol just before he closes the bladder, I heartily indorse.

Dr. William E. Stevens, San Francisco: I have been using electrocoagulation or surgical diathermy almost exclusively during the last six years, and I believe that it has much to offer in the treatment of tumors of the bladder. Several grade 3 cases are interesting. One patient with an infiltrating squamous cell carcinoma is in good health five years and five months after operation. Major Ash of the Army Medical Museum states that the tumor in this case shows more keratinization than any of the others in the registry and that the aforementioned period of nonrecurrence is remarkable. Another patient with a grade 3 tumor, infiltrating in type, died from other causes but free from recurrence one year after operation. A patient with a grade 3 papillary carcinoma is free from recurrence four years and three months after operation. Another with the same grade and type of carcinoma died following an operation for gallstones but free from recurrence of the bladder tumor one year and three months after operation.

Dr. John K. Ormond, Detroit: I have not had the wide experience that some of these other gentlemen have, but I have made it a practice to make sections of whatever tumors I see, and they have been classed according to the Broders classification in every instance. I have been surprised in some cases in which I have taken a specimen and then destroyed through the cystoscope by electrocoagulation to find that the growths were classed as Broders 4, and yet the patient remained well. I think that these cases fall into two classes, the pedunculated and the sessile, and that practically all the pedunculated tumors, unless they are very large, can be treated through the cystoscope. I have even treated several quite large growths of this type with good success. The diffuse, papillomatous tumors cannot, of course, be treated in this way, nor can the sessile tumors, but some rather large pedunculated growths can be successfully treated by fulguration. The point came up in connection with electrocoagulation that this procedure never causes any trouble even if the opening of the ureter is destroyed. I wish to ask Dr. Corbus whether the removal with the radio knife is comparable in that way. I have one patient for whom I removed a tumor with the radio knife who has a stricture of the orifice of the ureter.

Dr. Arthur L. Chute, Boston: I think that the older method of the operative removal of tumors of the bladder has not had quite a fair hearing. There is still so much that is not known about these tumors that I do not believe it is wise to give up entirely a method that has given a certain number of good results. I can think at once of three patients who have lived ten years or more and who are clinically well after the surgical removal of tumors of the bladder. These tumors were not classified according to the classification of Broders and their relative malignancy is not known, which is likewise the fact in many of the cases treated with radium or fulguration. One patient, a woman, aged 67, I operated on in 1913, removing a mass reported as a squamous cell carcinoma, surrounding one ureter and reimplanting the ureter. This patient was reported as well in 1929, sixteen years after operation. In the fall of 1917, I excised a mass on the right side of the bladder of a man, aged 64. It was macroscopically "carcinoma" according to a competent pathologist. This man was reported by one of his friends as well in 1930, thirteen years after operation. In February, 1918, I removed a considerable part of the left lateral wall of the bladder of a woman, aged 52, reimplanting her left ureter. This patient was reported as well within the past year. The mass was clinically an infiltrating one. I cannot find a definite microscopic report on it. These results I believe compare favorably with the best results obtained by irradiation or fulguration. I think that discrimination should be used in this work and radical removals should be done. Radium, as I understand it, acts satisfactorily only for about the distance of 1 cm. It seems to me that with surgical measures one can do better than that in many instances, and I cannot believe that the use of radium or fulguration about the ureter is good practice. I think surgery will give the best results in many cases, and that as a whole the use of radium and fulguration should be confined to cases in which it is believed that no radical operation can be done.

Dr. Waltman Walters, Rochester, Minn.: I agree with Dr. Chute that one must not overlook the fact that segmental resection of the bladder in cases of tumors involving the lateral walls and the dome completely removes the lesion if metastasis has not occurred. If the tumor involves the base of the bladder, however, radium implantation or electrocoagulation of the tumor or the actual cautery may be preferred; these may be used either singly or in conjunction. In the Mayo Clinic, the use of diathermy, in cases in which the tumor involves the base of the bladder, has been more satisfactory than the use of radium. In the classification of tumors of the bladder, the various degrees of malignancy should be taken into consideration. So also should the electrocoagulation in the destruction of a tumor be standardized. I think it is quite important that, in addition to the size of the tumor and its degree of malignancy, the size of the active electrode used in the electrocoagulation, the duration of treatment to the entire area of the tumor and the current used should all be recorded. There is no reason why a tumor cannot be completely destroyed if it is possible to estimate definitely the depth of the growth and approximately the depth and penetration of destruction of tissue by electrocoagulation and the degree of sloughing that will occur. The prognosis in these cases, I think, as has been so often repeated, is dependent on whether metastasis occurs and whether complete destruction or removal of the tumor takes place. As has been mentioned today, the fact that in a given case a malignant tumor of the bladder is graded 4 should not deter one from carrying on necessary surgical procedures.

Dr. Hermon C. Bumpus, Jr., Rochester, Minn.: During the discussion following this symposium on tumors of the bladder, there has been no reference to the patients with a malignant growth who live beyond the three or five year cure period without having received any form of treatment. In any large group of cases, from 2 to 5 per cent of patients will live this length of time no matter what form of treatment, or lack of treatment, they may have received. It is this group that forms the basis for such claims as have recently issued from San Francisco, and every physician must be on his guard to discount his results and not be deceived by the 3 to 5 per cent of patients who live more than from three to five years.

Dr. H. D. Caylor, Bluffton, Ind.: I think that a great deal of the fear in the classing of a so-called papilloma as an epithelioma is because it has been called a papilloma, which is actually a benign tumor; but if one analyzes these tumors, their gross and microscopic appearances, and the way they behave after an incomplete removal, I think that one will come to the opinion, whether agreeing with Broders or not, that a true benign papilloma of the bladder is very rare. Many of the growths that have been called papillomas were actually epitheliomas or whatever one wishes to name them. Dr. Barringer's remark about Dr. Ewing's using only three grades I think is a matter of opinion. I believe that four grades give a little better separation. If one wants to make it so simple one soon will have only two grades and then be back at the old position of just benign and malignant. The case that the doctor mentioned was apparently a relatively benign tumor and thus the patient lived a long time after fulguration. It must be remembered that most of the grade 4 tumors have the poorest blood supply of any of the different grades. There is little stroma, the blood supply does not keep up with the growth, and that perhaps is the reason the highly malignant tumors are so sensitive to radium, as Dr. Max Cutler and Dr. James Ewing have pointed out in regard to the highly malignant tumors that develop in the neck.

Dr. B. S. Barringer, New York: I wish to differ, very gently, from Dr. Caylor that one part of the tumor invariably shows the grade of all. I think it has been shown that from one site carcinoma can be obtained and from another site papilloma, and while tumors do run to form pretty well throughout, there are certain tumors which do not and one gets different pictures in different portions of the growth. I am sure Dr. Caylor did not mean that papilloma is very rare. Regarding operation, I think Dr. Keyes made an interesting statement some time ago, that a malignant operation should not be used for a malignant disease. I believe there is good sense in that. Dr. Corbus brought out a keen point that I have always believed. That is, that those who believe in diathermy should stick to that method. If one believes in surgery one should stick to that, and if one believes in radium therapy one should stick to that; and, finally, by comparing results with the bureau in Washington, one will get down to some idea of what is really the best method. Dr. Bumpus said two things. He mentioned a case of carcinoma of the bladder which had gone five years. I can better that a good deal. One patient has gone twelve or fifteen years with absolutely no treatment. She developed, after I saw her, a vesicovaginal fistula and I transplanted the ureter and she is alive now. I wish, however, to call the attention of Dr. Bumpus to the fact that these cases are very rare. Most of them go on to a fatal termination within a short time.

Dr. Budd C. Corbus, Chicago: Answering Dr. Ormond, I believe that the tumor situated near the ureter is more important than the ureter itself. It is burned "back" when necessary. If necessary, a ureteral meatotomy is done after the tumor is destroyed. I have a small silver ureteral catheter, about 2 inches long, and when I can put this into the ureter without too much traumatism I find that it keeps the ureter open and gives adequate kidney drainage during the time of the healing of the coagulated tissue. It is later removed by means of a small string attached to one end. I have found in several cases that the tumor extends up around the ureter for some distance.

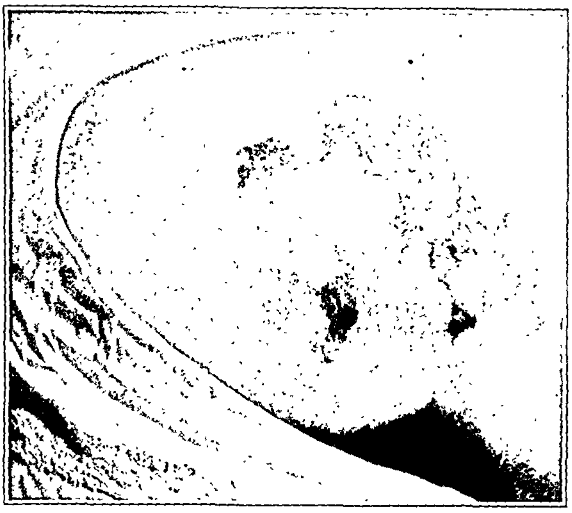
Recognizing Possibilities of Error.—Refinement in the technic of analyzing phenomena thus constitutes the sole difference between the scientific and the popular method of drawing conclusions. In adjusting any mechanical device, one may be exercising a very common kind of sense. But it is a sense which differs from that exhibited by the scientific investigator, only in so far as the facts examined by the investigator are the more complicated and can be approached only after extended preparation. The man who builds a concrete sidewalk in his yard learns by experience and experiment, and by thinking things out as he goes. The investigator who is trying to advance our knowledge regarding the chemistry of cement does essentially the same thing. Only he begins far ahead of the untrained man; and, having a broader knowledge, he recognizes possibilities of error that the other does not comprehend. The conclusion that we reach is, therefore, that there is nothing really unique in science or in the method of science. Scientists are not wizards but men who apply to natural phenomena the methods of analysis used by logical minds in the affairs of daily life.—Saidla, L. E., and Gibbs, W. E.: Science and the Scientific Mind, New York, McGraw-Hill Book Company, Inc., 1930.

Clinical Notes, Suggestions and New Instruments

EMBOLIA CUTIS MEDICAMENTOSA: LOCAL ARTERIAL EMBOLISM FOLLOWING THE INJECTION OF MERCURIC SALICYLATE IN OIL *

E. A. Skolnik, M.D., and Ruben Nomland, M.D., Chicago

The unintentional injection of oily suspensions of mercury or bismuth into an artery of the buttock is a very rare accident in the treatment of syphilis. Gammel [1] has reviewed the literature and reported five cases in his two papers on this subject. In the less severe cases there was only immediate severe pain, followed by induration of the buttock and bluish, reticulated mottling of the overlying skin. These conditions disappeared in about two weeks. In the severe cases there were extreme immediate pain, high temperature, constitutional symptoms, local induration, persistent soreness and reticulated, bluish discoloration of the skin. Occasionally sloughs formed, leaving ulcers. The external genitalia, bladder, vagina and rectum were sometimes involved. Nerve injury with paralysis of some of the leg muscles has occurred. In the excised tissue Gammel [2] demonstrated the heavy metal in the lumens of the cutaneous arterioles. He thought that the incidence of such accidents was about 1 in 15,000 intragluteal injections and that they could be avoided by proper technical precautions.



Appearance of buttock two weeks after injection of mercury in oil.

REPORT OF CASE

The following case is the only one known to have occurred at the Central Free Dispensary, where thousands of intramuscular injections are given yearly. The history is as follows:

A woman, aged 27, had received without mishap many intramuscular injections of a soluble bismuth compound during a year of intensive antisyphilitic treatment. The accident followed the first injection of 0.06 Gm. of mercuric salicylate suspended in 0.67 cc. of olive oil, given into the right buttock according to the usual technic. She stated that there was more pain than usual on the insertion of the needle and, immediately after the injection, a feeling as if her buttock had been scalded. However, she did not complain but went home. A half hour after the injection she said that the area looked and felt like a severe bruise. That night she felt chilly and had a "feverish" headache and backache. She remained in bed at home for a week with milder constitutional symptoms. When she returned for observation two weeks after the injection the buttock was still tender and painful. In addition to doughy infiltration of much of the buttock, there was an area 8 by 10 cm. of purplish, reticulated mottling of the skin as shown in the illustration. In the center of the discolored area there was a superficial, moist erosion, as though bullae had been present. A week later a slough had separated from the center leaving a shallow ulcer 2.5 cm. across. By this time most of the deep infiltration had disappeared. One month after the injection the ulcer was almost healed, but a reticulated, brown pattern of the lesion remained. There was no pain and scarcely any induration of the affected buttock.

SUMMARY

This case illustrates a rare, but classic, accident in intramuscular therapy, occurring when heavy metals suspended in oil are inadvertently given into a deep artery supplying the skin.

SURGERY IN MOVING PICTURES *

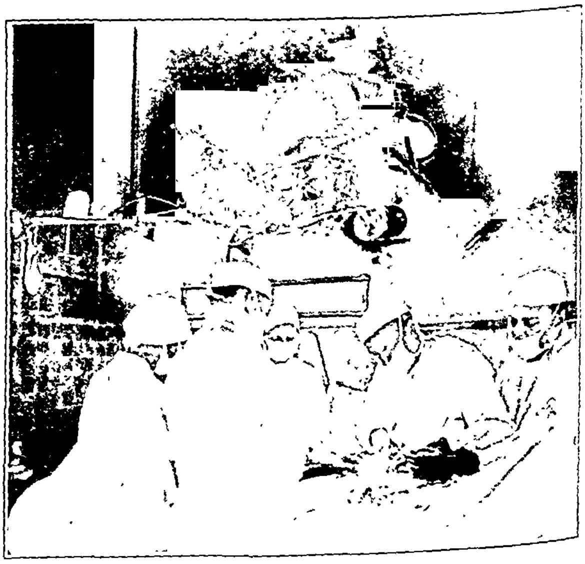
Richard B. Stout, M.D., Madison, Wis.

Surgical practice lends itself admirably to the taking of motion pictures to perpetuate the transient phases of operative technic. Unfortunately, many difficulties confront a camera man who may want to photograph an operation in progress.

First of all, the surgeons cannot be inconvenienced by the intrusion of photographic equipment. In any case, the camera man is kept so far away from the sterile field that his film usually records more elbows and backs than it does the operation.

To record what the surgeon sees and does, the camera is best placed somewhere above the patient but far enough away not to interfere with the surgeons or nurses. The accompanying illustration shows how a 16 mm. Filmo camera was attached to a regular Operay light, which may be conceded as being one of the most logical positions for it. To do this, an iron ring was fastened between the main lens of the lamp and frame. This ring was made with a projecting piece to which the Filmo camera was fastened.

As the camera was then out of reach, a remote control was necessary and a solenoid electromagnet was designed which could be fastened over the release button on the camera and controlled by a foot switch. This solenoid was made by winding a small brass tube in which a small soft iron armature was attached to the upper end by a spring. When the switch is pressed the armature is pulled down, operating the starting button and permitting the taking of single frames or longer exposures at will. The surgeon or his assistant may thus be



Making Kodacolor movies of an operation.

the camera man and take only the important steps of the operation.

As the camera spring must be rewound if more than 25 feet of film is to be exposed, the rewind device, shown in the illustration, was made. The shaft of a 4 inch V-grooved pulley was fitted to the winding key socket of the camera. Several turns of fine piano wire were taken around it and passed through a one-fourth inch flexible copper tube to a smaller wheel with a crank attached. A nurse may thus rewind the camera as necessary, from a distance.

Satisfactory black and white pictures may be taken at F 4.5 by the illumination of the ordinary operating light, but for Kodacolor pictures a considerable amount of auxiliary illumination is necessary. Eight small automobile spotlights were fitted with double filament 32-32 candle power 8 volt bulbs, all of which were connected in series and attached to the operating light by the arms shown. The series of auxiliary lights were then connected in multiple with the electromagnetic camera release and both controlled by the foot switch and operated on the 110 volt lighting current. Heat generated by the lights during the thirty to sixty second "shots" ordinarily taken is not objectionable. The low voltage lamps used generate far less heat than the regular type of lamp, so that water cooling is unnecessary.

The light emitted by incandescant lights has more red and yellow in its composition than daylight, so allowance has to be made accordingly when Kodacolor pictures are to be taken. This can be taken care of by reversing the ratio diaphragm that comes with the film so that the part that ordinarily masks the blue now masks the red portion of the Kodacolor filter. For our particular work, a little better color rendition was obtained by removing the ratio diaphragm entirely and covering a portion of the red side of the filter with a piece of black lantern slide binder.

A REAGENT FOR DEMONSTRATING FUNGI IN SKIN SCRAPINGS AND HAIR *

Theodore Cornbleet, M.D., Chicago

Fungous disorders of the skin are being seen in such increasing numbers that they are becoming a problem of public health. The first means of prevention is the quick recognition of existing cases. This can most rapidly and conveniently be done by knowing the distinct clinical forms which the different mycoses assume. While, to the expert, clinical means are generally sufficient, he too often needs the aid of the laboratory to be certain of his diagnosis. It is natural, therefore, that improved methods for demonstrating fungi in keratotic structures should be desirable.

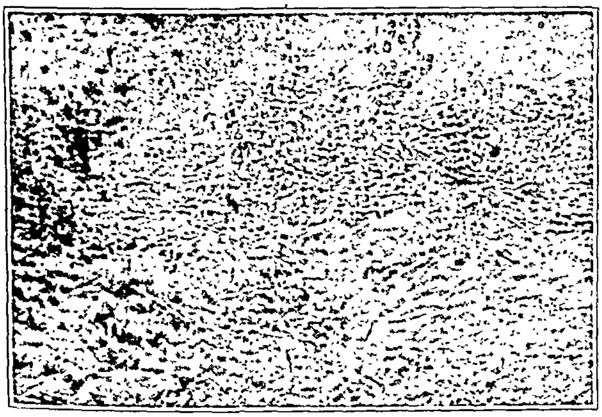

Fig. 1.—Fungi in scalp hair, 25 per cent solution of sodium hydroxide.

There are two laboratory procedures in general use by physicians for examining the skin and hair for fungi. The first is the cultural means and the second is the direct method of maceration with fixed alkalis. The cultural method does not lend itself to routine use by the physician because it requires too much time, material and special information. In the direct method most generally used today, the material to be studied is placed in several drops of a 10 to 40 per cent aqueous solution of potassium hydroxide on a glass slide and overlaid with a cover slip. After an interval to allow the keratin to dissolve, the preparation is examined through a microscope. When a solution of potassium hydroxide is freshly prepared and warm, it is generally satisfactory. Even then, however, it may lead to confusion by forming soaps with the oil that is present in the material under examination. These soaps may sometimes simulate fungous structures. Of course, this oil may be removed, but its complete removal offers some difficulty, as will be brought out hereafter. Another objection to solution of potassium hydroxide is that in the weaker concentrations it absorbs atmospheric carbon dioxide to form the relatively insoluble carbonate. Thus a relatively obscuring medium, which cuts down visibility, is employed. A third and serious objection to this reagent is the difficulty with which the hyphous and mycelial elements are seen through it. It is generally easy to see the spores, but in many cases the thallus or vegetative portion of the fungi is difficult to demonstrate. The latter structures usually show up either poorly or not at all, and it is the presence of just these vegetative portions of the organism that is usually relied on for making the diagnosis, since spores may be so easily confounded with artefacts. It would seem, therefore, that in spite of the ease with which fixed alkali reagents are prepared there still is room for other more efficient reagents, even though they are more difficult to prepare.

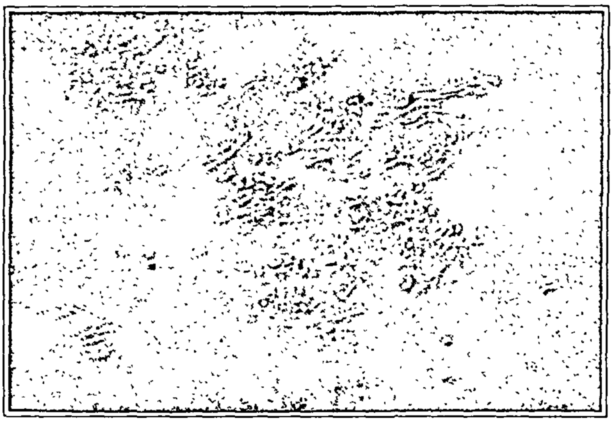

Fig. 2.—Fungi in scalp hair, sodium sulphide reagent.

There are several substances which seem to be as good as or better than an aqueous solution of potassium hydroxide. They either dissolve the keratin or cause its refractive index to contrast well with the highly refractile fungi. Some of these are trichloracetic acid, acetic acid and boiling glycerin. Perhaps the best keratin solvents are found in the sulphides of the fixed alkalis and alkaline earths. The reagent that is presently to be described includes the sodium sulphide.

FORMULA AND PREPARATION

Several drops of water are sufficient to dissolve a relatively large quantity of sodium sulphide crystals. Equal parts of this solution and 95 per cent alcohol are added to each other. A cloudy precipitate forms at once. Then, by adding a sufficient quantity of distilled water drop by drop, this precipitate redissolves and remains in solution. This completes the preparation. The reagent should be kept in a glass-stoppered bottle that is coated with paraffin at its neck. The alcohol content of the formula will remain relatively more constant if care is taken to close the bottle when it is not in use.

The alcohol serves a useful purpose in not only removing the oil at the surface of the keratin but also that which is between the scale layers. It does this because it is miscible with water. In this respect it is superior to ether, which is prevented from penetrating the interior by the water in the keratin. The alcohol also helps to attain just that refractive index which gives the optimum visibility of organism structure and transparency of

---

medium. Since the preparation is an unstained one, recognition of form depends on the difference in the refractive index between the examining medium and the organisms suspended in it. A medium that has the same refractive index as the organisms gives the greatest transparency but poor visibility, while a medium that has a lower refractive index gives a greater visibility of structure but diminished transparency. In making up the reagent, these two factors were considered, so as to get the optimum point for both. The index of refraction of keratin dissolved in a 20 per cent aqueous solution of potassium hydroxide is 1.363, while the index of a similar solution of keratin in the sodium sulphide reagent has an index of 1.382. The sodium sulphide reagent dissolves the keratin to produce a clear solution.

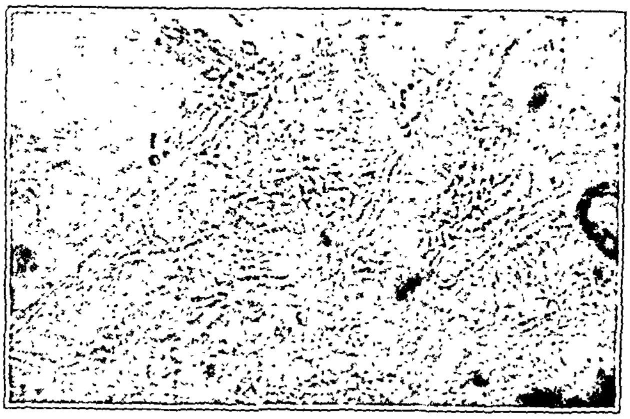

Fig. 3.—Microsporon furfur in skin scraping, 25 per cent sodium hydroxide.

USE

If it is not inconvenient, the scales and hair should first be soaked in ether to remove their surface oil. Otherwise they may be placed directly on a glass slide and covered with a cover slip. Several drops of the reagent are then run beneath the cover slip. Almost at once the keratin structures begin to swell and flatten out after they have made contact with the reagent. In a minute or two the cover slip may be gently pressed down to hasten the clearing process. From five to ten minutes is quite sufficient to produce enough clearing for a good examination. With a solution of potassium hydroxide, several hours is often necessary to obtain satisfactory clearing. Through the microscope the field shows up clearly and the vegetative structures are seen easily and distinctly as much thicker strands than are found when potassium hydroxide is used. Likewise, there are many more of them apparent than are seen when the fixed alkalis are used. The walls of the fungi are seen as brilliant blue or green borders that enclose delicately reticulated bands of internal structure.

HEPATODIAPHRAGMATIC ADHESIONS AS A CAUSE OF UPPER ABDOMINAL PAIN

J. William Hinton, M.D., New York
Assistant Professor of Surgery, New York Postgraduate Medical School and Hospital; Assistant Attending Surgeon, Bellevue Hospital; Assistant Attending Surgeon, St. Mark's Hospital

When patients present symptoms of chronic pain referable to the right upper quadrant with acute exacerbations, one immediately thinks of a diseased biliary or genito-urinary tract and possibly a gastric or duodenal ulcer associated with chronic pancreatitis. If these are excluded, one's attention is directed to the cardiovascular or central nervous system or to diseases of the vertebral column; if after careful clinical and laboratory studies no cause can be found to account for the pain, the patient may be considered a psychoneurotic.

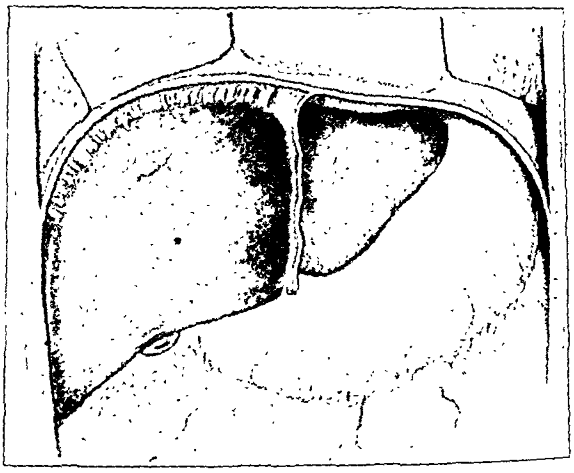

Fig. 1.—Anterior view of adhesions between liver and diaphragm.

Curtis[1] recently called attention to adhesions in the right upper quadrant as a sequela of a gonorrheal infection in females. He describes them as violin string or banded adhesions occurring between the anterior surface of the liver and the anterior abdominal wall. In the case I encountered in which the operation was performed before Curtis published his recent observations, the adhesions were between the liver and the diaphragm with the pain referable to the right kidney region. The patient had been roentgenographed and told she had a kidney stone, some months before entering the hospital, and was admitted with that diagnosis for operation.

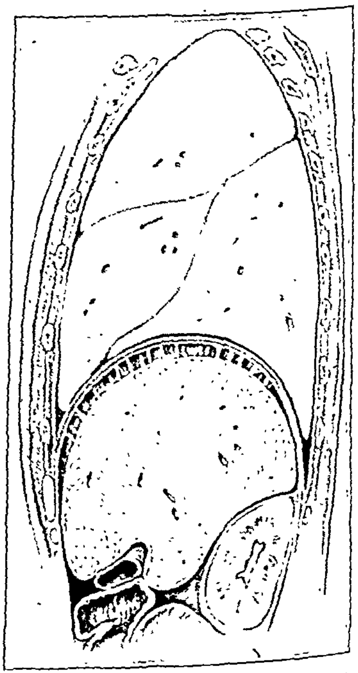

Fig. 2.—Lateral view of adhesions between liver and diaphragm.

REPORT OF CASE

History.—A woman, aged 29, admitted to the Fourth Surgical Division of Bellevue Hospital, March 2, 1930, complained

---

1. Curtis, A. H.: A Cause of Adhesions in the Right Upper Quadrant, J. A. M. A. **94:** 1221 (April 19) 1930.

chiefly of severe pain over the right kidney and the right upper quadrant. The patient was married and had one child, aged 10 years. About one year after the birth of her child she began having pain over the lower part of the abdomen associated with a white discharge; the pain was more severe in the right lower quadrant. Four months after onset of the pain she entered a hospital in the suburbs of New York and had a curettage without improvement; then, two months later, Sept. 16, 1921, she entered Bellevue Hospital complaining of a white discharge and pain in the lower part of the abdomen which had been severe for two weeks. A diagnosis of chronic salpingitis, bilateral, and endocervicitis was made.

The patient was treated conservatively with improvement and was discharged, September 26. She continued to have abdominal discomfort for the next year and was operated on in November, 1922, in the Receiving Hospital in Detroit at which time the right tube, the right ovary and the appendix were removed.

Present Illness.—The patient stated that she had had pain in the right upper quadrant and the kidney region since before her operation in November, 1922. This pain was at first of a dull character but it gradually became worse, at times being quite severe, in her right side. Nine months before admission the pain became very severe and the patient came to the outpatient department at Bellevue Hospital and after clinical and roentgen examination was told that she had a kidney stone. She continued to have discomfort, which was growing gradually worse until three days before admission to the hospital, when she had very severe pain in the right costovertebral angle associated with a feeling of frequency of urination, but she did not void. The pain also radiated around to the vulva. During the past few months she had lost 12 pounds (5.4 Kg.).

The patient also gave a history of having been hit over the lower right side of the chest while she was coasting fourteen months before. This accident, however, did not incapacitate her at the time.

Examination.—There was definite tenderness of the right costovertebral angle and lower right part of the chest in the midaxillary line, but no gallbladder or abdominal tenderness. Otherwise the examination was negative. March 4, 1930: Roentgenograms of the genito-urinary tract were negative for calculi. March 7, roentgenograms of the chest were negative. March 10, cystoscopic examination and pyelograms were negative with a note that the urologic tract was not impaired. March 15, the dye test revealed that the gallbladder was normal. March 19, a gastro-intestinal series was negative. The Wassermann reaction, blood counts, and urine examinations were negative. The patient continued to complain of severe pain in the right kidney region and over the lower right side of the chest, so an exploratory operation was decided on.

Operation and Result.—March 27, the abdomen was opened through an upper right rectus muscle splitting incision. The gallbladder was of normal color, not thickened, and no stones were palpable. The stomach and duodenum were normal and the pancreas was not enlarged. The small intestine was then inspected and found normal. The appendix was found to have been removed at the previous operation; the large intestine appeared normal to palpation. The uterus was of normal size, the left tube and ovary normal to palpation with a moderate number of adhesions in the pelvis as the result of the previous operation. The right kidney was of normal size and firmly fixed. When the hand was passed over the dome of the liver, many firm adhesions were found between it and the diaphragm; these were more numerous over the posterior surface of the liver. There were no adhesions between the liver and the anterior abdominal wall and the adhesions described would not have been detected unless the hand had been passed over the liver. The left kidney was palpated and found of normal size and firmly fixed with the spleen and left lobe of liver normal to palpation.

It was felt after the exploration had been completed that the symptoms were referable to the hepatodiaphragmatic adhesions, and these were divided by a blunt dissection. A moderate amount of bleeding ensued, which was controlled by hot packs. The abdomen was then closed in anatomic layers without drainage. The exact location of the adhesions is given in the illustrations.

Postoperative Course.—The patient made an uneventful convalescence with the exception of a slight wound infection and was discharged from the hospital, symptom free, April 19.

The patient was last seen, June 19, at which time she was symptom free except for a slight discomfort over the left lower quadrant which was referable to the chronic pelvic infection.

COMMENT

After the completion of the roentgenograms and laboratory studies on this patient she would have been discharged without operation except that her complaints of her original pain were so serious that an exploratory operation was felt to be justified without any conception of what might be the exact cause of the patient's discomfort. The observations of Curtis have again proved that one must not neglect a careful history in arriving at a final diagnosis even in the face of negative roentgenographic and laboratory observations.

125 East Seventy-Second Street.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, Secretary.

ANTIPNEUMOCOCCUS SERUM (See New and Nonofficial Remedies, 1930, p. 351).

The National Drug Co., Philadelphia.

Antipneumococcic Serum, Type I.—Marketed in packages of one 50 cc. double-ended vial with apparatus for intravenous injection.

ERYSIPELAS ANTISTREPTOCOCCUS SERUM.—A specific serum containing the antibodies and antibacterial properties of *Streptococcus erysipelatis.*

Actions and Uses.—For therapeutic use against erysipelas. It may be of value when administered in adequate doses in the early stages of the disease. Though there is no evidence for the value of nonspecific antistreptococcus serums, there appears to be some evidence for the value of a serum representing the antigenic and antibacterial properties of *Streptococcus erysipelatis.*

Eli Lilly and Company, Indianapolis.

Erysipelas Antistreptococcic Serum-Lilly (Concentrated Globulin).—The serum is obtained from horses immunized with strains of hemolytic streptococci obtained from human cases of erysipelas. It is concentrated by a method similar to that employed in the refinement of diphtheria antitoxin, the resultant serum containing both neutralizing and bacterial antibodies. Marketed in packages of one syringe containing an average initial therapeutic dose.

Dosage.—The contents of one syringe.

PSYLLIUM SEED (See New and Nonofficial Remedies, 1930, p. 311).

Richards Psyllium Seed.—A brand of psyllium seed-N. N. R.

Prepared by Richards Pharmacal Co., Inc., New York.

SCARLET R MEDICINAL BIEBRICH (See New and Nonofficial Remedies, 1930, p. 147).

The following dosage form has been accepted:

Ointment Scarlet Red Biebrich 8 Per Cent. Scarlet R medicinal Biebrich-N. N. R. 8 per cent in an ointment base consisting of stearin 5 per cent, wool fat 25 per cent, and petrolatum 70 per cent.

Prepared by the National Drug Co, Philadelphia.

TYPHOID VACCINE (See New and Nonofficial Remedies, 1930, p. 373).

The National Drug Co., Philadelphia.

Typhoid-Paratyphoid A Vaccine (See New and Nonofficial Remedies, 1930, p. 377).- Also marketed in packages of three 1 cc. vials each containing 750 million killed typhoid bacilli and 250 million killed paratyphoid A bacilli per cubic centimeter.

SATURDAY, DECEMBER 6, 1930

THE WHITE HOUSE CONFERENCE ON CHILD WELFARE

Elsewhere in this issue (page 1765) appears an extended account of the reports made available by the White House Conference on Child Welfare, held in Washington in November. Most of the newspaper reports covering the occasion emphasize the attempts of various interests to take advantage of the conference to promote a campaign for a children's bureau separate from other health activities. As is usually the case, the element of conflict thus introduced dominated the publicity rather than the constructive efforts exemplified in the well considered reports of committees that had been giving thought to the problems of child welfare, child health and education for the past year. In the care of the child lies the future of the nation; in the control of the education of the child and in the establishment of its habits early in life lies the secret of its happiness in later years. The disposition among psychologists, psychiatrists, social workers and specialists in various medical fields to separate their individual problems from the consideration of the whole baby is one of the destructive tendencies of the times. Superspecialization in the adult is a serious problem, notwithstanding the fact that the adult, through an understanding mind, is able frequently to ward off some of the evils associated with consideration of an organ, a tissue or a system within his body rather than with the human being as a whole The child, unable to think for himself, succumbs readily to lopsided control, so that the body and mind may be distorted by superspecialization in its handling. In a great conference, such as that which has just been held, it is possible for all the various interests to come together and to exchange their views—indeed, to be forced into a realization that the child must be considered as a human being and not as a mental case, a handicapped arm, a case in malnutrition or a problem in behavior.

The present administration of the government is apparently committed to unification of control in public health. Committees in the White House Conference charged with the consideration of administrative methods recommended that the health of the child be not separated from other problems of public health but that it be brought properly under the attention of the United States Public Health Service. In an attempt at a revision of this point of view, women's clubs, welfare organizations and indeed every possible influence that could be brought to bear were asked to telegraph to the conference in favor of the establishment of a special department of the government for the care of the child separate from the United States Public Health Service. On short notice and without thorough consideration of all the motives and principles underlying the matter, many organizations sent their telegrams. Fortunately, the conference was so organized that it could not be stampeded by any such method.

The immediate, practical outcome of the White House Conference is hard to determine. It had the advantage of causing several thousands of persons especially interested in the problem of child welfare to analyze and to coordinate their views. It caused the entire nation to be, for at least one week, child-minded. It will bring about, no doubt, the dissemination of much educational material to the public. The progress of a movement so auspiciously and expansively initiated will be observed with interest.

MEMORIAL FOR PHYSICIANS WHO SERVED AND DIED IN THE WAR

In Paris today there is being constructed a memorial building, called Pershing Hall, planned to preserve in sculpture, painting and historical mementoes America's participation in the war. The Army, the Navy, the Marine Corps, the National Guard, the Engineers, the American Field Service, the Red Cross, the Knights of Columbus, the Salvation Army, the Jewish Welfare Board, the Elks and the Daughters of the American Revolution have each contributed from ten thousand to twenty-five thousand dollars for special halls in this building dedicated to their respective services. Princeton, Harvard, Yale and a number of other universities also have established in this building memorials to their war dead. As representative of the American medica profession, the American Medical Association has been asked by the sponsors of Pershing Hall to contribute ten thousand dollars for furnishing and decorating a salon in this building devoted to the commemoration of the physicians who served and died. It is understood tha this great building, now almost completed and costing approximately a million dollars, will house a grea historical library, an auditorium and other facilities a an American center in Paris. There American children will be able to come for classes in English, civics and American history, and a center will be available fo distribution of information to Americans visiting Paris

The Board of Trustees of the American Medica Association, after giving careful consideration to the request to devote ten thousand dollars from the funds of the Association to the establishment of a medical salon in Pershing Hall, recognized the opportunity here available for a spontaneous contribution by physicians throughout the country who desired to be individually of assistance in sponsoring this project. The raising of ten thousand dollars by some forty-eight state medical organizations as component parts of the American Medical Association should be no great task. Therefore, the Board of Trustees authorized a special committee consisting of Dr. William Gerry Morgan, Dr. Olin West and the editor of The Journal to place this project before the medical profession and to request from the members of the profession individual contributions of from one to twenty five dollars for this purpose. All contributions will be acknowledged and a list of contributors will be made available in the *American Medical Association Bulletin*. A book containing their names will rest permanently in the salon in Pershing Hall. On advertising page 38 in this issue of The Journal appears a further announcement of this project, together with a coupon to be used in sending in the contribution.

No word need be said—indeed, it is doubtful whether any words might be said—that would fittingly record the service rendered by the medical profession in the great conflict. No memorial can be builded that will suitably memorialize the supreme sacrifice made by those who died in their attempt to salvage the wreckage of the greatest war the world has ever known. It is fitting, however, that, in this great memorial to be erected in Paris, some record should be available of those who served the medical profession and the nation. It is desirable that the American Medical Association, through its membership representing the vast majority of the medical profession, should sponsor the raising of the ten thousand dollars necessary to furnish, decorate and maintain the salon in which the information concerning the work of the profession in the war will be permanently available. Even in times of financial depression the majority of physicians will be able to devote one dollar to such a memorial and many will be glad indeed to contribute ten, twenty or twenty-five dollars for such a cause. It might well be that the faculties of medical colleges, the staffs of hospitals and clinics, and physicians organized in county medical societies, or in such organizations as the Association of Military Surgeons and the Medical Veterans of the World War, may wish to contribute their donation in sums representing the organization. All such contributions will be specially acknowledged in The Journal and in the *Bulletin*.

The Trustees of the Association would be gratified to be able to notify the sponsors of Pershing Hall before January 1 that the medical profession had welcomed the opportunity to contribute and had completed its donation in less than thirty days. THE COUPON APPEARS ON ADVERTISING PAGE 38.

ICTERUS NEONATORUM

The line of demarcation between the physiologic and the pathologic is sometimes indistinct, as in icterus neonatorum. Biliary pigmentation, as a rule, is the expression of an abnormality in the excretion of bile or in the breaking down of hemoglobin. Visible jaundice of the new-born infant occurs so frequently, however, that many physicians have concluded that it must be a normal physiologic process. Statistical tabulations place the incidence of icterus neonatorum at from 20 to 80 per cent of all normal new-born infants. It occurs more frequently in premature than in full-term infants. Usually it is manifest on the second to the fifth day of life but disappears spontaneously by the end of the second week of life. This spontaneous recovery without ill effects also suggests that jaundice of the new-born is a physiologic state. Nevertheless the cause and the nature of the pigmentation have always challenged intelligent curiosity.

A variety of divergent views and theories have been offered. Virchow early in his scientific career expressed a view that foreshadowed the present conception, but later he abandoned it. In the second of two lectures on the excretion of uric acid by the fetus and the new-born infant, delivered before the Berlin Obstetric Society, Nov. 24, 1846, he said that the establishment of independent respiration, digestion and heat regulation at birth is a revolution that marks the emancipation of the child from the mother and is characterized by important chemical and physical changes in the blood. Among these changes is increased destruction of red blood corpuscles, from whose liberated hemoglobin bile pigment is formed. He then asked a question that may be freely translated as follows: "Is it not natural to look on icterus neonatorum, which is held to be a disease, as merely an increase in a physiologic process, whose excess reveals itself by manifestations that are less stormy at earlier and later periods of life?" Ten years later, in an annotation to this lecture when it was included in a collected reprint[1] of his early writings, he had receded from his clairvoyant position and found it necessary to ascribe icterus neonatorum to catarrh of the duodenum and bile passages. It had become a pathologic condition not essentially different in its pathogenesis from catarrhal jaundice of the adult.

To the weight of this authority, three decades later, the weight of the Minkowski and Naunyn dictum "Ohne Leber kein Icterus" was added, based on their classic experiments on bile formation in geese. Since the formation of bile pigment required the activity of the liver, it followed of necessity that icterus neonatorum must be due to a disturbance of this hepatic function. But morphologic evidence of such disturbance of function, except the patent jaundice that is an end-result, could not be readily adduced. The duodenal and biliary catarrh described by Virchow, the pigment thrombi of the bile canaliculi described by others, or intrahepatic biliary stasis due to temporary portal congestion resulting from the adjustment of the circulation from the fetal to the postnatal type could not be detected with sufficient uniformity to offer a satisfactory explanation.

[1] Virchow, Rudolf: Ueber Harnsäure-Abscheidung beim Fötus und Neugebornen: Gesammelte Abhandlungen zur wissenschaftlichen Medicin, Frankfort a. M., Meidinger Sohn & Co., 1856, p. 833.

The introduction by Hijmans van den Bergh of the Ehrlich diazo reagent as a qualitative and quantitative test for bilirubin in the blood and fluids of the body presented a new method for the study of abnormalities in biliary pigmentation. By the application of this method it has become possible to distinguish between an increase due to bilirubin that has already entered or passed through the liver cells, the resulting jaundice being of an obstructive and reabsorptive type, and an increase due to bilirubin that has not yet been subjected to the activity of the liver cells, the resulting jaundice being nonobstructive. Knowledge of biliary pigmentation has been further clarified by the study that has been given to the functions of those cells and tissues that have come to be grouped together as the reticulo-endothelial system. By the activity of these cells, hemoglobin derived from the destruction of erythrocytes may be transformed into bilirubin. It has become necessary to recognize that anhepatic formation of bilirubin may occur and that forms of jaundice that are shown by the van den Bergh reaction to be nonobstructive may be hematogenous in origin.

Proof of the extrahepatic formation of bilirubin has led to renewed interest in the genesis of icterus neonatorum. Schultz,[2] working in Aschoff's institute in Freiburg, used the microchemical detection of iron in the tissues of new-born infants as a criterion of increased red blood corpuscle destruction, which might lead to jaundice. In three fetuses of the third to sixth month of pregnancy, obtained at necropsy of women in whom labor had not begun, the cells of the reticulo-endothelial system were free from iron. In all infants, whether full-term or as premature as those mentioned, whether born dead or alive after labor had been initiated, there was erythrophagocytosis by the cells of the reticulo-endothelial system and deposition of iron in these cells. Apparently the mechanism of delivery initiates changes in the body of the child that lead to increased destruction of erythrocytes and to formation of bilirubin from their derivatives by the reticulo-endothelial system. Aschoff and Hummel,[3] in a study of premature and full-term stillbirths and live births, noted some interesting peculiarities of the bilirubin of such infants. Most striking was the crystallization of bilirubin in the blood and body fluids and in the tissues. Such a phenomenon has been noted only rarely in jaundice that develops at some time after birth, and then only in jaundice of hematogenous origin of the type to which Aschoff has applied the term hyperfunctional icterus. The van den Bergh reaction of the blood was the indirect one of bilirubin of extrahepatic origin and was more intense than normal even in the absence of visible jaundice. The contents of the biliary passages and intestine of still-born infants gave an indirect reaction; in infants that lived for a while, the reaction was both direct and indirect. Aschoff and Hummel interpret their results as proof of the extrahepatic formation of bilirubin in new-born infants and in icterus neonatorum.

If the increased bilirubin formation in the body of the new-born infant is due to increased and perhaps physiologic destruction of red blood corpuscles beginning during or immediately after birth, the reason for such increased destruction remains to be determined. Schultz associated the phenomenon with the initiation of delivery. Red blood corpuscles are seen so frequently in the cerebrospinal fluid of new-born infants as to suggest that a moderate degree of extravasation of blood from the capillaries of the body may be almost a physiologic effect of the mechanism of labor. This process might account for the degree of erythrophagocytosis and iron pigmentation noted by Schultz in nonjaundiced infants, but it would have to be extreme, that is, pathologic, to account for the degree of jaundice not infrequently seen in icterus neonatorum. Goldbloom and Gottlieb [4] found that the blood of all new-born infants yields an indirect van den Bergh reaction, visible jaundice being merely a matter of the degree of extrahepatic bilirubin formation. That the erythrocyte count of new-born infants is high, as compared with that of children and adults, has long been known. Goldbloom and Gottlieb observed a rapid decrease of this polycythemia. The decrease in the number of red corpuscles began during the first twenty-four hours after birth and reached its maximum within the first week of life, the erythrocyte count becoming stabilized by the latter half of the second week. In vitro tests proved the fragility of the erythrocytes to be greater during the period of decreasing polycythemia than later. The immature erythrocytes, the nucleated and reticulated red blood cells, are more fragile than the mature ones and disappeared from the circulating blood during the early days of life. In a series of sixty-one new-born infants, Mitchell [5] of the University of Pennsylvania has also reported a progressive decrease in the erythrocyte count from the first to the tenth day after birth, but he noted that the depth of jaundice was not always proportional to the decrease in the number of erythrocytes. The degree of bilirubinemia and of jaundice is probably a resultant of three variables, the degree of destruction of red blood corpuscles, the degree of activity of the reticulo-endothelial system, and the degree of secretory activity of the liver cells.

[5] Mitchell, J. M.: Relationship of Jaundice and Weight to Blood Values in the New-Born Infant, Am. J. Dis. Child. **38**: 518 (Sept.) 1929.

Goldbloom and Gottlieb at McGill have presented a plausible explanation of the polycythemia of the new-born infant and of its rapid disappearance. Because of the nature of the fetal circulation, the fetus lives in a state of relative anoxemia, a state which, as in post-natal life, demands a high number of erythrocytes for the transport of the available oxygen. With the establishment of a separate arterial and venous circulation at birth, the necessity for polycythemia disappears and the more immature and more fragile red blood corpuscles quickly disappear from the blood. Their destruction leads to physiologic hyperbilirubinemia that may manifest itself as visible jaundice.

The physiologic character of icterus neonatorum warrants the textbook statement that this form of jaundice does not require treatment, but it should not be permitted to blind the physician to the fact that other forms of jaundice the prognosis of which is much more grave may also develop in the early days of life. Obstructive jaundice may be due to inflammation of the duodenum or biliary passages or to congenital anomalies of the biliary tract, and jaundice of hematogenous origin may be due to sepsis or to congenital familial hemolytic icterus. A half century ago Violet[6] made a distinction between jaundice of the new-born, icterus neonatorum, a physiologic state, and jaundice in the new-born, icterus in neonato, a pathologic condition, a distinction stressed also by Aschoff and Hummel.

Current Comment

ROENTGEN DIAGNOSIS OF SYNOVIAL ADHESIONS

Following fifteen years of patient experimentation, another unusual chemical adjunct to roentgen diagnosis seems to be available. With this new aid, altered permeability of synovial membranes can be determined and accurate pictures secured of synovial adhesions. Demonstrations of abnormal synovial permeabilities were made about sixteen years ago by Dr. Henry Keller,[7] orthopedic surgeon of the Neurological Hospital, New York, who injected easily diffusible dyes into joint cavities and followed their subsequent excretion by the kidneys. To modify this test so as to obtain at the same time roentgenograms of joint cavities, it was necessary to find or synthesize a nontoxic chemical substance readily excreted by the kidney, and of sufficient density to cast a distinct shadow on the x-ray plate. Many substances were tried. One compound was found suitable. This substance is a disodium salt of tetraiodo-orthosulphobenzoic acid. This sodium salt is odorless, tasteless, and readily soluble in water, an 11.3 per cent solution being isotonic with human blood. The isotonic solution is nonirritating when instilled into the conjunctival sac of the human eye. Injection into laboratory animals does not cause local irritation. Intravenous injections are well borne by them and the injected drug is rapidly excreted by the kidneys. Kidney function is not impaired. With ordinary concentrations, no depression is demonstrable with isolated smooth muscles. Albino rats previously trained in a circular maze do not show impairment of memory on administration of the new drug or alteration in neuromuscular control. Injected into joint cavities of dogs, the new compound gives sharply defined x-ray shadows of joint cavities. After this extensive pharmacologic study the new compound was tested clinically and it is reported to have fulfilled all expectations. In addition to being of interest to orthopedic surgeons, this diagnostic victory is an ideal example of ethical medical research. Detailed study was made on lower animals before clinical application was attempted.

THE 1930 NOBEL PRIZE IN MEDICINE

Karl Landsteiner, since 1922 a member of the Rockefeller Institute for Medical Research in New York, is the recipient of the 1930 Nobel Prize in Medicine. Since the beginning of his scientific career, more than thirty years ago, Landsteiner has made contributions of great significance to medical science. He has thrown much new light on the nature of paroxysmal hemoglobinuria. With Popper he first produced infantile paralysis in the monkey, a demonstration that was followed by the intensive experimental work to which we owe practically all that is known of the nature of the causative agent of the disease. Undoubtedly Landsteiner's greatest and most brilliant work is his study through many years of fundamental problems in immunity, particularly the chemistry of the specificness of immune reactions. In this field, that is, the relations of the mechanisms of immunity to chemical structure, he has been and is a great leader, making no hasty or extravagant claims but standing always on solid ground. The main motivation for awarding to him the Nobel Prize in Medicine appears to have been his discovery of the human blood groups or the phenomenon of iso-agglutination. His first statement about human iso-agglutination appears in a footnote to an article[1] in 1900 about the antifermentative, lytic and agglutinating actions of the blood serum and lymph. In this footnote he says that the serum of normal persons agglutinates not only the blood corpuscles of animals but also the corpuscles of other persons. It remains, he continues, to determine whether this phenomenon depends on natural, individual differences or on injurious influences perhaps of bacterial nature. In fact, he had found the action especially pronounced in blood from patients with severe diseases. Before long he demonstrated conclusively by careful observations that iso-agglutination depends on individual, physiologic differences in the blood. Here was a concrete and clean-cut discovery that was destined to have wide applications. Landsteiner himself early pointed out the possibility that iso-agglutination might prove of importance in the identification of blood for medicolegal purposes and also in blood transfusion. The practical use of blood grouping, now universal, to exclude incompatible donors in therapeutic transfusion was initiated and developed especially in this country. When it became established that the factors on which blood grouping depends are transmitted according to the laws of heredity, determination of the blood groups was applied to the study of interracial relationships and of problems of parentage. When Landsteiner described the blood groups, he was an assistant under Weichselbaum in the pathologic-anatomic institute of the University of Vienna. No doubt he little thought then that that work was to bring him such rich reward thirty years later, but he did the work and carried out the observations as carefully and accurately as he could without any consideration or motive other than to find out all in his power about something new and obscure. Thus his work became the starting point in a series of advances in knowledge and achieved its international and well merited recognition.

Association News

THE PHILADELPHIA SESSION

The Scientific Exhibit

The Scientific Exhibit for the Philadelphia session of the American Medical Association, June 8-12, 1931, will be located in the Philadelphia Municipal Auditorium.

The Committee on Scientific Exhibit emphasizes again the necessity of presenting exhibits in a manner that will stress their scientific value. This may be done by carefully worded explanatory placards or legends, and particularly by personal demonstration by the investigator himself. The committee feels that the Scientific Exhibit offers unusual opportunity for investigators and visiting physicians to meet and discuss informally the phases of the research being presented. Also it should be remembered that general attractiveness is essential. The committee will do its part by providing attractive booths decorated appropriately. Uniform illuminated signs giving the name of the exhibitor and the title of the exhibit will be furnished, as well as a uniform shelf with covering.

Application blanks for the Scientific Exhibit may be obtained by sending requests for them to the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

Applications must be received before Feb. 20, 1931. In order that the amount of space available may be apportioned to the best advantage to all concerned, the committee will make no assignments previous to March 10; nor can large blocks of space be assigned to individual exhibitors.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10:15 on Tuesday, 10:30 on Thursday and 10 on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

December 8.	Preventing Death from Cancer.
December 9.	Hay! Hay!
December 11.	Dust.
December 13.	What Can Be Done About Whooping Cough?

Five minute health talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

December 8.	Give the Baby a Chance.
December 9.	Unsuspected Dangers.
December 10.	When Winter Comes.
December 11.	What Shall We Do with Garbage?
December 12.	Physical Fitness.
December 13.	Can It Be Done?

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Research on Mussel Poisoning.—Investigation of the occurrence of poisoning in mussels and clams of the Pacific Coast which led to the illness of sixty-two people and the death of four in July and August, 1929, was recently completed by the University of California Hooper Foundation for Medical Research. It was found that the Pacific Coast mussel contains minute traces of a poison throughout the year, but that it is apparently dangerous only during the months of July and August. Attempts to locate the source of poison met with little success. Tests of other shell-fish in the vicinity of the mussel beds failed to reveal poison.

Narcotic Violations.—At the regular meeting of the California State Board of Medical Examiners in Sacramento, October 21-22, the following physicians were placed on probation for the periods indicated, having been found guilty of narcotic violations: Drs. George H. Bland, Fresno, five years; Dwight D. Johnson, Grass Valley, three years, and James T. Murray, five years, during which time they shall not apply for or have a narcotic permit nor have narcotics in their possession, and Fred H. Van Tassell, Berkeley, one year, following a hearing based on narcotic derelictions. Dr. Murray's restriction applies to alcohol also. The following physicians' licenses were revoked for narcotic convictions: Drs. Archibald A. Atkinson, North Sacramento; James Terrell Brown, Los Angeles; Samuel D. Cottrell, Los Angeles; Ernesto Scosseria, San Francisco, and Newton B. Siler, Los Angeles.

FLORIDA

Personal.—Dr. Walton H. Y. Smith, formerly of the health department of Tampa, has been appointed health officer for the Taylor County unit.——Dr. Henry Mason Smith, Tampa, was recently selected as president of the Florida State Board of Health; Dr. Henry E. Palmer, Tallahassee, was appointed to succeed Dr. William D. Nobles, Pensacola, resigned, and Dr. Edward M. L'Engle, Jacksonville, to succeed Hon. C. H. Mann, Jacksonville.

GEORGIA

Society News.—Dr. Herbert B. Kennedy, Atlanta, gave a clinical talk, November 20, before the Fulton County Medical Society at Atlanta on "Why People Consult a Physician," and Dr. William P. Herbert, Asheville, N. C., spoke on "Surgery as an Aid in the Cure of Pulmonary Tuberculosis." Drs. George W. Fuller and Dunbar Roy presented case reports on "Retroperitoneal Mixed Tumor" and "Unilateral Total Ophthalmoplegia Externa," respectively.——The Chatham County Medical Society was addressed at Savannah, October 28, by Dr. Walter A. Norton on "Spontaneous Rupture of the Liver."——The Georgia Urological Association was addressed at Atlanta, October 30, by Drs. Henry W. E. Walther, New Orleans, on "The Urologist's Attitude Toward the Neuroses and Functional Disorders of the Urogenital Tract"; Russell A. Hennessey, Memphis, Tenn., "Traumatic Lesions of the Urinary Organs," and Owsley Grant, Louisville, "The Place of the Punch in Prostatic Surgery—Report of Fifty Consecutive Cases."——The state board of health will soon begin work on a $3,700 school building at Alto for the children who are inmates of the tuberculosis sanatorium; plans have also been approved for a similar building for the Negro children.

INDIANA

Personal.—Dr. Amos Carter has announced his retirement from active service as superintendent of the state sanatorium at Rockville, a position which he has held for eleven years. For a number of years he was staff physician of the state boys' school at Plainfield. He began practice in 1878.

Society News.—Dr. Robert B. Preble, Chicago, delivered a paper on "Generalizations Concerning Heart Diseases," November 13, before the Tippecanoe County Medical Society, Lafayette.——The Terre Haute Academy of Medicine was addressed, October 23, by Dr. Edward L. Keyes, New York, on "Preoperative Measures to Be Used in Lessening Mortality in the Prostatic."

IOWA

Lectures on Obstetrics.—Dr. Everett D. Plass, professor and head of the department of obstetrics and gynecology at the State University of Iowa College of Medicine, Iowa City, will deliver ten lectures on obstetrics in December. The course consists of lectures, lantern slides and manikin demonstrations, and is composed of ten lectures of two hours each on the following topics: Contraception and Contraceptive Methods; Disease Complications of Pregnancy; The Management of Normal Labor; Hyperemesis Gravidarum; motion pictures — Podalic Versions; Induction of Abortion and of Premature Labor; Forceps Version Breech Extraction; Cesarean Section; Hemorrhage and Puerperal Infection. A registration fee of $20 will be charged. Physicians interested in this course should communicate with the University of Iowa School of Medicine.

KANSAS

Society News. — The Clay County Medical Society was addressed, September 17, by Dr. Earle G. Brown, Topeka, on public health.——Dr. Justin A. Blount, Burdett, addressed the Rush-Ness County Medical Society, September 10, on "Factors in the Consideration of Diarrheas of Infancy."——The Dickinson County Medical Society was addressed at Abilene, October 23, by Dr. Herschel R. Turner, Hope, on basal metabolism.——Dr. Laurence P. Engel, Kansas City, addressed the Bourbon County Medical Society, October 20, on the surgical treatment of goiter, and Dr. Peter T. Bohan, Kansas City, Mo., goiter heart.

MARYLAND

Dr. Stokes's Memory Honored. — The unveiling of the bronze memorial tablet of Dr. William Royal Stokes in the municipal building, Baltimore, took place, November 26. Dr. C. Hampson Jones, commissioner of health, presented the tablet to Baltimore. It was erected to Dr. Stokes's memory by the physicians and other employees of the Baltimore City Health Department. Dr. Stokes, who was director of laboratories of the city and state departments of health many years, died of psittacosis. Addresses were made by Drs. William H. Welch, professor of the history of medicine, Johns Hopkins School of Medicine, and Dr. Hugh S. Cumming, surgeon general, U. S. Public Health Service.

Society News. — Dr. Edward A. Looper gave a moving picture demonstration of removal of foreign bodies from the esophagus and bronchi before the Baltimore County Medical Society, November 19.——Dr. William C. White of the U. S. Public Health Service gave a public lecture on "Acid-Fast Bacteria, Their Relation to Disease and the Need for Better Preventive Measures," November 25, at Johns Hopkins University; his lecture was one of the De Lamar course in hygiene.——At a meeting of the Baltimore City Medical Society, November 21, in Osler Hall, a major portion of the entire group of 300 house officers of the hospitals of Baltimore City were received into membership. Dr. Lewellys F. Barker addressed the meeting on "Work of the Resident Staff of the Hospitals in Baltimore and Its Significance for Subsequent Medical Careers."

MICHIGAN

Society News.—Madame N. Dobrovolskaya-Zavadskaya of Madame Curie's laboratory, Paris, France, addressed a joint meeting of the Washtenaw County Medical Society and the University Roentgen Ray Society, Ann Arbor, November 19, on "The Heredity of Cancer." The Wayne County Medical Society was addressed, November 18, by Madame Dobrovolskaya-Zavadskaya on "Biological Basis for the New Conception of Life."——Dr. George E. McKean, Detroit, addressed the Jackson County Medical Society at Jackson, November 18, on treatment of hypertension.——Drs. R. E. Logan and Robert L. Novy addressed the heart committee of the Tuberculosis and Health Society of Detroit and Wayne County, November 14, on "The Cardiac Child at School" and "Developing a Normal Personality," respectively.

Dr. Pritchard Goes to Welfare Foundation. — Dr. J. Stuart Pritchard, for many years on the staff of the Battle Creek Sanitarium, has resigned to become medical adviser to the W. K. Kellogg Child Welfare Foundation, recently established for the rehabilitation of undernourished children. Dr. Pritchard will be retained on the sanatorium staff as consultant. His place as director of the chest department will be filled by Dr. James K. M. Gordon, his associate for the past five years. Dr. Pritchard was appointed representative of the U. S. government at the International Conference on Tuberculosis recently held at Oslo, Norway, but was unable to attend.

MINNESOTA

School Superintendent Violates Basic Science Law.—Edward L. Schmidt of the public school board at Meadow Lands was sentenced, November 20, to pay a fine of $500 or spend three months on the St. Louis County Work Farm, after entering a plea of guilty to a charge of practicing healing without a basic science certificate. The defendant has persisted for the last three years in treating people for various ailments, and investigators found various medicinal preparations, including chloroform and ether, in his possession besides a stethoscope, thermometers, artery forceps and other surgical instruments. Schmidt had been acting as health officer in three towns in the vicinity and was receiving $450 a year for that service. He had been warned on two occasions but continued in the business. The sentence was stayed until further order by the court.

Society News.—The Minnesota Radiological Society was addressed at Minneapolis, October 25, among others, by Drs. Walter H. Ude on "Roentgen Studies on the Onset of Lobar Pneumonia"; Harry M. Weber, Rochester, "Air Injection in the Diagnosis of Lesions of the Colon"; following an informal dinner, which was attended by Drs. James M. Martin of Dallas, Texas, and Bernard H. Nichols, Cleveland; Dr. Edward Schons, St. Paul, among others, spoke on "Significance of Small Intestinal Gas in the Diagnosis of Bowel Obstruction."——The Minnesota Society of Internal Medicine was addressed, among others, by Drs. Albert M. Snell, Rochester, on "An Unusual Deficiency Syndrome Secondary to Duodenal Occlusion"; George E. Fahr, Minneapolis, "Theoretical Features Particularly in Regard to the Normal and Disturbed Kidney Function"; Morse J. Shapiro, "Principles Underlying the Recent Attempts at Classification of Arthritis"; Norman P. Johnson, "An Unexploited Therapeutic Opportunity in Periodic Health Examinations of Young Adults," and Lewis M. Daniel, "A Study of Migraine in University Students." The evening session was addressed by Charles Sheard, Ph.D., Rochester, on "Energy."——A series of lectures on cardiologic subjects was begun by Dr. George E. Fahr, Minneapolis, on "The Management of the Ambulant Cardiac Patient" before the Park Region District and County Medical Society, October 8, in Alexandria.

NEW JERSEY

Aged Practitioner Honored. — Dr. Asher T. Applegate, Englishtown, who has practiced medicine for nearly sixty years in Englishtown and vicinity, was honored, October 5, by the presentation of a silver loving cup by former Governor A. Harry Moore in recognition of his long and faithful services to the community. Dr. Applegate has been mayor ever since Englishtown became a borough. He now is 84 years of age and is still actively engaged in medical practice.

Society News. — Dr. Max H. Bochroch, Philadelphia, addressed the Cumberland County Medical Society, October 14, on "Cerebrospinal Syphilis," and Dr. Harry Lowenburg, Philadelphia, "Practical Pediatrics."——The eye, ear, nose and throat section of the Academy of Medicine of Northern New Jersey was presented with an illustrated address on "Headaches and Systemic Disorders of Nasopharyngeal Origin" by Dr. Simon L. Ruskin, New York, October 13.——"Hypertensive Cardiovascular Disease" was the subject of Dr. Edward Weiss, Philadelphia, before the October 11 meeting of the Gloucester County Medical Society.——Dr. Delmer Allan Craig, Chicago, addressed the Hudson County Medical Society, October 7, on "Important Points in Safeguarding the Future of Medical Practice."——The Middlesex County Medical Society was addressed, October 15, by Dr. John F. Hagerty, Newark, on "Clinical Observations in Diseases of the Thyroid Gland."——Dr. Lester H. Hummel, Salem, addressed the annual meeting of the Salem County Medical Society, October 22, at Salem on "Bacteriologic Factors in the Cause of Common Colds."——The clinical session was inaugurated at the Hackensack Hospital, Hackensack, October 3, with a clinic and lecture by Dr. Winfield Scott Pugh, New York, on "Physical Methods in Urology."

NEW YORK

Society News. — Dr. Bernard S. Denzer, New York, addressed the Medical Society of the County of Queens, November 21, on "Treatment of Common Anemias in Infancy and Childhood"; the society was addressed, October 28, by Drs. Joseph S. Thomas, Flushing, and John Matthew Scannell, Jamaica, on "Diagnosis of Acute Surgical Diseases of the Abdomen" and "Blood Transfusion," illustrated, respectively.

Neuropsychiatric Problem Clinic Established. — The neuropsychiatric problem clinic for minor mental and nervous disorders, to be conducted jointly by the Albany Medical College and Albany Hospital, was opened recently. Sciences relating to effects of mental conditions or body ailments will have an important part in the work of the department. It will be headed by Dr. Lloyd H. Ziegler, professor of neuropsychiatry in the college and hospital, and assisted by Dr. Hugh T. Carmichael and Dr. Nelson K. Fromm. Dr. Fromm will conduct a neurologic clinic for cases in which the nervous disorder is due primarily to body ailments rather than mental troubles. In general the clinic will provide free service for persons who cannot afford to pay for private treatment by a specialist. The department will provide a new avenue of study for nurses and students, will give practicing physicians in Albany and northeastern New York an opportunity for graduate study in this field, and will expand local facilities for research work. The addition of two research fellows to the department will be provided for as soon as funds are available.

New York City

University News.—Edward S. Harkness has recently increased the endowment of Columbia University's department of surgery by a gift of $600,000, which places the department on a full university basis. The latest donation follows other large ones from Mr. Harkness, which includes the $4,000,000 site for the medical center; $2,000,000 for a residence hall at the center in 1929, and $500,000 on October 9. One million dollars was also given by Mr. Harkness to Western Reserve University Medical Center.

Pediatric Department Reorganized.—The Children's Medical Division of Bellevue Hospital, with practically the entire staff of the service, was transferred from Columbia University to New York University, July 1; this service has a census running from 100 to 175, average about 140 patients. There are six wards, one each for the following: infants with infections; infants without infections; acutely ill older children; one each for boys and girls with chronic or subacute illness; and one for gonococcus infection complicated by other illness. A special ward for tuberculosis is under construction. Every bed is in a cubicle. In the near future the outpatient department will move into a new modern building with ample room for the large attendance. Most of the teaching of pediatrics will be done on this service with some courses at City Hospital, Roosevelt Hospital and the Willard Parker Hospital for Contagious Diseases. The department has been reorganized with Dr. Charles Hendee Smith as professor of pediatrics and director of the Children's Medical Division.

Conference to Reorganize Disease Terminology.—The National Conference on Nomenclature of Disease, represented by fifty delegates from twenty national societies, met, November 24, at the New York Academy of Medicine, for the consideration of eliminating confusion in medical circles over the names of certain diseases. The conference was first formed two years ago by the initiative of the public health relations committee of the New York Academy of Medicine and is composed of representatives of various national medical organizations. In an effort to prepare an authoritative nomenclature of diseases in which all the diagnostic titles will bear a clear and unquestioned significance, a new system was proposed. In this a new disease will be classified in two ways: according to the part of the body affected and according to the cause that produces it. The method proposed by the national conference carries the analysis of causation much further than any other in that when the cause is unknown the disease is classified by the structural or functional changes which the disease produces, and this will be defined in its title.

Society News.—Under the auspices of the pediatric department of the Brooklyn Jewish Hospital, Brooklyn, a series of lectures in pediatrics and cognate sciences will commence, December 23, in the auditorium of the Dr. Leon Louria Memorial; Dr. Isidore Friesner will speak on "Middle Ear Infections in Childhood and in Infancy."——The Medical Association of the Greater City of New York was addressed, November 17, by Drs. Charles G. Kerley and Thurman B. Givan on "The Relation of Appetite Failure in Infants and Children to Defective Gastro-Intestinal Mechanics" and "Differential Diagnosis of Congenital Syphilis," respectively.——The speakers before the Yorkville Medical Society of the City of New York, November 17, were Drs. Joseph B. Wolffe on "Vasodilator Extract in the Treatment of Vascular Diseases with Special Attention to Angina Pectoris"; Aaron E. Parsonnet, Newark, N. J., "Myocardosis, the Failing Heart of Middle Life," and Albert S. Hyman, "Irregularities of the Fetal Heart: A Phonocardiographic Study of the Fetal Heart Sounds from the Fifth to Eighth Months of Pregnancy."——Dr. Pol N. Coryllos addressed the American-Hungarian Medical Association, November 18, on "Surgical and Clinical Aspects of Bronchial Obstruction."——The New York Physicians Association was addressed, November 19, by Drs. Albert A. Berg and Isidore Friesner on "Neoplasms of the Colon" and "Otological Conditions of Interest to the General Practitioner," respectively; Mr. Morris L. Ernst spoke on "Morals in Relation to Law."——The Bronx County Medical Society was addressed, November 19, by Drs. Francis Carter Wood on "Modern Cancer Research"; Maurice Lenz, "Radiotherapy in Cancer," and George Henry Semken, "Modern Cancer Surgery."——"Poliomyelitis Horse Serum: Its Preparation and Use" was the subject of Dr. Marcus Neustaedter before the Medical Society of the County of New York, November 24.——Dr. Cary Eggleston addressed the South Brooklyn Medical Society, November 20, on cardiovascular diseases.——Dr. James William Hinton addressed the New York Surgical Society, November 26, on "Bleeding Gastric and Duodenal Ulcers."——The Pan American Medical Association, New York chapter, was addressed by Drs. John B. Deaver, Philadelphia, on "The Pancreas," and Ernst Herzfeld, Buenos Aires, "Surgical Treatment of Echinococcus of the Lung."

PENNSYLVANIA

Society News.—At the annual conference of component society secretaries, December 2, Pittsburgh, addresses were made by Drs. Harold L. Foss, Danville, on "Hospitals as Educational Centers," and William H. Ross, Brentwood, president of the Medical Society of the State of New York, "A New Force in Organized Medicine." Besides the secretaries of the county societies, the editors of their bulletins and the officers and trustees of the state society were present.

Philadelphia

Coordination in Tuberculosis Work.—The formal opening of the headquarters of the newly organized Philadelphia Association of Tuberculosis took place, September 29. The association includes twelve city and eleven private institutions. This marks the first coordination of the work of all of its chest clinics. The organization is the result of a report made by Dr. Haven Emerson, New York, following a survey of Philadelphia hospitals and health. It was pointed out that there were duplications of the work of tuberculosis clinics in some sections of the city, while less adequate results were being accomplished in other sections. The association will define the areas in which each clinic will operate in order to facilitate the attendance of patients for examination and treatment. A definite limit will be placed on the duplication of work done by clinics and nurses. The organization will develop a system of referring patients from clinic to clinic for the convenience of employed patients who need to go to night clinics. The object will be to keep patients under observation until satisfactorily cared for in either a sanatorium or a hospital and to observe them further after their return from such institutions.

TENNESSEE

Special Training for County Health Officers.—Five doctors of medicine, four of whom expect to enter public health work in Tennessee, are now engaged in a twelve weeks' graduate course in preventive medicine in Vanderbilt University. They are Drs. William C. Sanford, Ripley; Preston H. Edwards, Jr., Darlington, S. C.; Hainan C. Busby, New Albany, Miss.; John Y. O'Daniel, Laurens, S. C., and Alfred Larson. The university course, consisting of six weeks, will be supplemented by field training in county health departments. The course is offered every October and April and covers all branches of public health work.

Society News.—The Nashville Academy of Medicine was addressed, November 4, by Dr. Robert F. Lischer, Mascoutah, Ill., on "A Pen Picture of the Country Doctor."——The Robertson County Medical Society was addressed in Adairville, Ky., October 28, by Drs. Samuel C. Cowan and Harrison H. Shoulders, Nashville, on "Rectal Analgesia in Obstetrics" and "Cholecystitis," respectively.——The Chattanooga and Hamilton County Medical Society was addressed, among others, recently by Dr. John Marsh Frere on "The Roentgen Ray in Traumatic Surgery."——Dr. Roger N. Herbert addressed the Davidson County Medical Society, October 21, on "Reflex Pain with Reference to the Rectum"; Dr. Thomas Fort Bridges addressed the society, November 11, on "Premature Infants: A Report of 118 Cases."——"Mediastinal Tumors" was the subject of an illustrated address before the Hardin, Lawrence, Lewis, Perry, Wayne Counties Medical Society, October 28, by Dr. Ray C. Bunch, Nashville, and "Placenta Praevia" that of Dr. Paul H. Faucett, Columbia; Dr. Granderson H. Bradley, Nashville, spoke on "Consideration of Some of the Common Ailments of Children."

TEXAS

Society News.—The Dallas Academy of Ophthalmology and Otolaryngology was addressed, December 2, by Drs. John O. McReynolds on "Optic Neuritis," and Charles P. Schenck, Fort Worth, "Intracranial Complications of Mastoid and Sinus Infections."——The Texas Pediatric Society was addressed at Fort Worth, October 28, among others, by Drs. *Herman P. Radtke*, Fort Worth, on "Orthopedic Treatment of Poliomyelitis," and Roy P. Forbes, Denver, "Use of Vaccines in Treatment of Children."——The Dallas County Medical Society conducted a symposium on peptic ulcer, September 25, the speakers being Drs. Gilbert E. Brereton, Harry G. Walcott and Charles W. Flynn, all of Dallas.——Dr. Gilbert E. Haslam, Ranger, addressed the Eastland County Medical Society, October 6, on "Middle Ear Infections."——"Clinical Importance of Nonsurgical Biliary Drainage" was the subject of Dr. Atmor S. Holley, Houston, before the Harris County Medical Society, September 30.——The Hidalgo County Medical Society was addressed, October 9, by Drs. Jason E. Montgomery, Weslaco, and William E. Whigham, McAllen, on "Paranasal Sinusitis" and "Cancer of the Cervix," respectively.——"Intravenous Urography with Uroselectan" was the subject of Dr. Eugene V. Powell, Temple, among others, before a recent meeting of the Lavaca County Medical Society.——Drs. Allen T. Stewart and Frank B. Malone, both of Lubbock, addressed the Lubbock-Crosby Counties Medical Society, October 7, on "Oxytocics, Past and Present" and "Lipiodol in the Diagnosis of Chronic Mastoiditis," respectively.——Dr. D. Leon Sanders, Wills Point, addressed the Van Zandt County Medical Society, October 3, on insanity, and Dr. Frank L. Lee, Ben Wheeler, presented a case report on quinsy.——The Second District Medical Society was addressed, among others, October 6-7, by Drs. Charles L. Martin, Dallas, on "Uterine Hemorrhage Without Demonstrable Pathology," and Ray M. Balyeat, Oklahoma City, on "Diagnosis and Treatment of Allergic Diseases," illustrated.

WEST VIRGINIA

"Dr." Bancroft Leaves Town.—Representatives of the West Virginia Medical Association have exposed a "Dr." C. Bancroft, who, in September, rented an office in Charleston, explaining that he was not a practicing physician but had agents who sent in customers for his electromedical appliances. One patient is said to have paid Bancroft $125 for "some extra special pills that had been put up in Germany and which could not be obtained anywhere in this country." The patient became violently ill, and the exposure of Bancroft followed. On being exposed, he left town. Physicians are advised to be on the lookout for "Dr." Bancroft, who may be operating under another name among foreigners. He is reported to be about 53 years of age, five feet eleven inches tall, weighing about 140 pounds. He has sandy hair and complexion and a rather anemic appearance. He looks like an American and speaks good English, but he also speaks other languages. He smokes cigarets constantly, and walks with a cane.

GENERAL

Openings for Interns.—The Hospital for Joint Diseases, New York, has announced six openings in house staff appointments for two years, rotating service in the various branches of practice. At the completion of the two years' service, graduating interns are eligible for the Frauenthal Travel Scholarship of $2,400 a year for six months' study in the leading clinics of Europe and six months' study in the United States, and the Mr. and Mrs. Frederick Brown Research Fellowships, with an income of $4,800, providing an award of $2,400 each to two successful candidates. Applications should be made to the director of the Hospital for Joint Diseases, Madison Avenue and One Hundred and Twenty-Third Street, New York.

Decline in Infantile Paralysis.—According to telegraphic reports from forty-six states and the District of Columbia to the U. S. Public Health Service, recently noted in the *United States Daily*, the "expected drop" in the number of cases of infantile paralysis has materialized. The disease has been continuously increasing since the middle of May, when twenty-six cases were reported, and reached the highest maximum in recent years during the week ended October 4, when a total of 647 cases was reported; the maximum number of cases, it was explained, reported for the calendar year 1929 was 146, and for 1928, 240. Of the 553 cases reported for the week ended October 11, Kansas still ranks highest with a total of 57. However, this represents a "notable decrease" from the 87 cases reported for the preceding week.

American Hospital Association.—At the thirty-second annual convention of the American Hospital Association, held in New Orleans, October 20-24, Dr. Lewis A. Sexton, Hartford, Conn., was installed as president; Mr. Paul H. Fesler, Minneapolis, was made president-elect, and Dr. Bert W. Caldwell, Chicago, was reelected executive secretary. The association now has 2,463 personal memberships and 1,426 institutional memberships. Interest centered around the series of round table discussions on group nursing as a means of reducing the cost of illness; the hospital's contribution to the advancement of scientific medicine, and the hospital's obligation to its local community. A new project of the association was the establishment of a research bureau on hospital development. In conjunction with this meeting was also held the fourteenth annual session of the American Occupational Therapy Association. Officers elected were Dr. Joseph C. Doane, Philadelphia, president, and Mrs. Eleanor Clarke Slagle, New York, secretary. The October 23 meeting of the Children's Hospital Association of America was addressed, among others, by Dr. Charles C. Hedges, New York, on the organization of a pediatric outpatient department, and Dr. Laurence R. DeBuys, New Orleans, the management of a children's service in a general hospital.

Syphilis Control Demonstration.—A report has been *recently made of the fifth syphilis control demonstration by* the Julius Rosenwald Fund cooperating with the North Carolina State Board of Health and the U. S. Public Health Service. The aim of the demonstration held in Pitt County, N. C., was an attempt to demonstrate the possibility of mass control of *syphilis in selected population groups, directed by Dr. John* J. Tyson of the state board of health. The population was assembled at certain centers on given days and hours. From April 1 to August 1, 10,198 primary Wassermann tests were taken throughout the county, including Greenville, of which *8,995 were negative and 1,203 were positive. Further taking* of Wassermann tests was discontinued because of the limit of the budget allowance and clinic staff. Wassermann tests were taken of family groups whenever possible, which accounted for the large number of cases examined at the age group 1 to 19 *years, which included 5,421 Wassermann tests, or 53 per cent* of the total number taken at the demonstration. Treatment centers were established at Bethel, Pactolus, Simpson, Ayden, Farmville and Greenville, with a clinic a week held at each place. About one fourth of the patients were treated Saturdays, *in the central clinic established at Greenville.* The average proportion of positive Wassermann reactions in Pitt County was 11 per cent, compared to 35 per cent in the demonstration at Macon County, Ala., previously. The comparatively low percentage of positive Wassermann reactions in Pitt County as compared with the Tuskegee, Ala., *demonstration shows* a wide difference in the intelligence and physical and social characteristics of the individuals. If the scope of the studies were enlarged to take in the entire Negro population of both counties, the total Negro population of Pitt County would probably show 2,840 positive Wassermann reactions in a Negro population of 24,000 and 7,000 population in Macon County. The fact that Pitt County has had a full-time health unit for many years and a state department of health is held responsible for the low incidence of the disease in this county.

PHILIPPINE ISLANDS

Leprosy in the Philippines.—Five hundred and fifty-three lepers were released on parole during the past year from the various hospital centers in the Philippine Islands. This makes a total of 2,013 released as negative *since 1922. In his annual* report as governor general of the Philippines, Dwight F. Davis stated, it is said, that the island government with the aid of the Leonard Wood Memorial for the Eradication of Leprosy is combating this once incurable disease with increasing success. Leprosy is still a serious problem, as one *third of the insular* appropriation of the health service is utilized in segregation and treatment of lepers. Treatment stations were opened during the year at Iloilo and in the Bicol region. A new one will soon be opened at Zamboanga, and the large station at Cebu is now functioning. The Leonard Wood Memorial, in addition to expending 360,000 pesos ($180,000) for the Cebu Leprosarium, released 285,000 pesos for use in Culion and 30,000 pesos for the erection of a skin clinic in Cebu. The Cebu station, with accommodations for 1,000 and facilities for the advancement of research in the treatment of disease, was made possible through a gift of Eversley Childs and is known as the Eversley Childs Treatment Station. His gift was largest, followed by $100,000 from John D. Rockefeller, Jr. With Culion, where 6,000 lepers can be accommodated, as the center of a campaign against leprosy, the general program of the memorial *organization contemplates the establishment of stations in vari-*

ous provinces and while fostering research in methods of producing and using chaulmoogra oil, improving the existing hospital facilities in Culion and Cebu, and assisting in the training and maintenance of a large staff of physicians and nurses to give treatment wherever it is needed in the islands.

CANADA

Personal.—Dr. Alfred K. Haywood has resigned as superintendent of the Montreal General Hospital, Montreal, to accept a similar position at the Vancouver General Hospital, Vancouver, B. C.

Osler's Memory Honored.—A magnificent stained-glass window and brass tablet were unveiled and dedicated to the memory of Sir William Osler in Trinity Church, Bond Head, September 30; the memorial was donated by the Simcoe County Medical Association. Osler was born in the old rectory, which stood one mile west of the church, and he was baptized in Trinity Church. The north transept of the church has been set aside as a memorial to the Osler family; Rev. Featherstone Lake Osler, the father of Sir William, founded the parish. Following the dedicatory ceremonies, the Simcoe County Medical Association convened in Orange Hall, Bond Head, where addresses were made by Drs. Fraser B. Gurd, Montreal, on "Modern Methods in the Treatment of Carcinoma"; Norman B. Gwyn, Toronto, compared the severe anginas of Osler's time with the coronary thrombosis of today, and Larimer J. Austin, Kingston, Ont., "Tuberculosis of the Kidney." The Osler oration was delivered by Dr. Campbell P. Howard, Montreal, who is the son of Osler's great teacher and companion, on the kindly relationship of Sir William to all with whom he came in contact.

Society News.—The Academy of Medicine of Toronto began, November 12, the second series of Wednesday afternoon lectures on subjects of special interest to the practitioner; Dr. Robert V. B. Shier spoke on that date on "Surgical Diagnosis and Differential Diagnosis of Acute Abdominal Conditions," and Hardolph Wasteneys, November 19, on "Vitamins"; future speakers and their subjects will be Drs. Andrew A. Fletcher, "Chronic Arthritis"; Arthur B. LeMesurier, "Osteomyelitis"; George E. Wilson, "General Principles in the Treatment of Fractures"; Alfred H. W. Caulfield, "Bronchiectasis, Its High Incidence in General Practice as Revealed by the Use of Lipiodol," and George R. Pirie, "Infant Feeding."——The eleventh Congress of the Association of French Speaking Physicians of North America, held in Montreal, September 16-19, was attended by between six and seven hundred delegates from Paris, London, Mexico and the United States. Features of the meeting were a visit to the St. Hubert Airdrome, where demonstrations were made of the medical side of aviation; clinical meetings at the Hotel Dieu and Hôpital St. Jean de Dieu; a demonstration of methods for thoracoplasty in tuberculosis by Dr. Edward W. Archibald, and a presentation of a plaque to Dr. D. Brochu, founder of the association. Dr. Brochu was for many years dean of the Faculty of Medicine of Laval University.

FOREIGN

Infant Mortality in Calcutta.—According to the *Weekly Bulletin* of the New York City Department of Health, the health officer of Calcutta reported for the year 1928 an unusually high rate of infant mortality. For the past ten years this rate has averaged above 300 per thousand live births. In 1928, out of 22,001 reported births, 6,138 infants died in the first year, a rate of 279 per thousand live births. In some new areas, the infant death rate was high; 207 infant deaths out of 385 live births, a rate of 539 per thousand; 219 infant deaths out of 514 live births, a rate of 426 per thousand, and 387 infant deaths out of 990 live births, a rate of 390 per thousand. Infant mortality is highest among the Mohammedans (393 per thousand) with Hindus second (261). It is lowest among non-Asiatics and Anglo-Indians; namely, 136 per thousand.

League of Nations Health Committee.—The sixteenth session of the League of Nations Health Committee, held September 29-October 7, was the first meeting of its reconstituted committee of eight new members out of a total of twenty-seven. Dr. T. J. M. Madsen, director of the Danish State Serum Institute, president of the Health Committee since its foundation in 1923, was reelected. The present position of the health organization was reviewed in the light of its ten years of activities. Among the branches of the league's health activities which passed through a period of study and collection of information before judgment was made and action started was the world-wide service of epidemiologic intelligence and public health statistics, and recommendations for combating malaria and the inquiry into infant mortality. The permanent standardization commission for devising and maintaining uniform international standards for the preparation and measuring of serologic and biologic products will be continued and kept up with the evolution of science, thought and method. The opium commission reported progress following the plans laid down by the Geneva Opium Conference of 1925. The leprosy commission has just completed a preliminary world survey. Partial surveys have been made of scarlet fever and diphtheria; continuation work will involve the fumigation of ships, special problems of infant mortality, especially in Latin America, smallpox, cancer and education in hygiene and preventive medicine. The activities concerning epidemiologic intelligence and a liaison with sanitary administration, particularly the system of interchanges or study tours for public health officers, formed the backbone of the health organization's work. The health committee appointed groups of experts to study, among other subjects, the proposal of the French government for the establishment of an international school of Advanced Health Studies in Paris, to be financed by an annual grant of one million francs. It was suggested by the league's system of study tours. The theoretical program will embrace general hygiene, an outline of the latest health knowledge and the organization and method of international health cooperation. Various scholarships and subsidies will be established. The council of the league will summon a European conference on rural hygiene at Geneva, April 23, 1931, at the suggestion of the Spanish government, on account of the importance of rural hygiene and agricultural reconstruction. In reporting the studies of the malaria surveys in India, it was said that this disease probably kills more than all other epidemics put together. As 90 per cent of India's population is rural, the crux of the problem lies in the 700 villages of this country. The cooperation of the Indian Health Service was commended. The report of the leprosy study in Europe, America and the Far East stressed the necessity of coopting the work of institutions and research workers over the world. In the health survey of Bolivia undertaken as assistance in the reorganization of its health service, the investigators traveled over an area three times the size of France and this included the experience of flying over the Andes at a height of 18,000 feet and their assistance to wounded citizens in street fights in the revolution. Other league projects were the antisyphilitic work in Bulgaria, inquiry into the health conditions of the Pacific Islands, the recommendations of the opium commission, and assistance in reorganizing the public health service in Greece.

Government Services

Army Personals

The following officers having been found by an army retiring board incapacitated for active service on account of disability incident thereto, and such finding having been approved by the President, their retirement is announced, effective October 31: Col. John L. Shepard, Majors Lewis Covington, Clinton L. Hoy and Daniel J. Hayes, and Capt. Kenneth G. Kincaid. Major Herbert H. Price and Capt. Francis E. Council will sail about February 4 and January 13, respectively, for duty in the Philippine Department; Capt. Seth Gayle, Jr., is assigned to duty in Alaska, effective in April, and Capt. Samuel Marcus to duty at Fort Benning, Ga.

Change of Station in the Navy

Lieut. Comdr. Erik G. Hakansson from the naval hospital, Pearl Harbor, T. H., to the naval hospital, League Island, Philadelphia; Lieut. Albert R. Behnke to the U. S. S. *Holland;* Lieut. Craig B. Johnson to the submarine base, New London, Conn.; Lieut. Comdr. Clarence W. Ross to the naval hospital, Pearl Harbor, T. H.; Lieut. Comdr. Victor S. Armstrong to duty involving flying, U. S. S. *Saratoga;* Lieut. Claude A. Angonnet from the Receiving Ship, San Francisco, to the naval training station, San Diego.

U. S. Public Health Service

Senior Surg. Hugh De Valin, relieved at Hot Springs, Ark., and assigned to duty at Ellis Island, N. Y.; Medical Director George L. Collins, relieved at Philadelphia, and assigned to duty at Washington, D. C.; Asst. Surg. Joseph O. Dean, relieved at Rosebank, N. Y., and assigned at Relief Station, Philadelphia; P. A. Surg. Joseph F. Van Ackeren, relieved at Naples, Italy, and assigned at Bergen, Norway.

Marriages

CHARLES PENNINGTON RYLAND, JR., Buena Vista, Va., to Miss Edith Elizabeth Finney of Washington, D. C., November 15.

ROBERT HOLMES LATIMER, St. Marys, Ont., Canada, to Miss Ruth Victoria Johnston of London, November 10.

CARL A. KARSH, North East, Pa., to Miss Ruth Lucille Pearson of Portville, N. Y., recently.

MAHLON C. HINEBAUGH, JR., to Miss Sidney E. Pollick, both of Philadelphia, September 3.

ARTHUR B. DAVENPORT, Pittston, Pa., to Miss Jessie Fassett of Tunkhannock, August 16.

MICHAEL H. BOLEY to Miss Florence Killilea, both of Milwaukee, November 25.

D. W. SHELLY, Ambler, Pa., to Mrs. Helen Edwards of Philadelphia, July 5.

Deaths

James Madison Kennedy ⊕ Brigadier General, U. S. Army, retired, Washington, D. C.; College of Physicians and Surgeons, Baltimore, 1892; entered the army as an assistant surgeon in 1893; advanced through the various grades to that of colonel in 1917; appointed brigadier general, assistant to surgeon general in 1927; served during the Spanish-American War; chief surgeon, division of Philippines, 1900-1902; formerly in command of the Letterman General Hospital, Presidio of San Francisco, and of the Army Medical Center, Washington; awarded the distinguished service medal during the World War; member of the American College of Surgeons; aged 64; died, October 15, in the Letterman General Hospital, San Francisco, of carcinoma of the pancreas with metastases to the liver.

Jonathan Currier, Grampian, Pa.; Kentucky School of Medicine, Louisville, 1881; member of the Medical Society of the State of Pennsylvania; for many years member of the school board; formerly member of the state legislature; aged 78; died, October 3, in the Clearfield (Pa.) Hospital, following an operation for intestinal obstruction.

William W. Perdue, Mobile, Ala.; University of Alabama School of Medicine, Mobile, 1908; member of the Medical Association of the State of Alabama, and American College of Surgeons; formerly clinical assistant in ophthalmology at his alma mater; served during the World War; aged 44; died, October 3, at Spring Hill.

Jean F. Wolfs ⊕ Newark, N. J.; Long Island College Hospital, Brooklyn, 1905; served during the World War; on the staffs of St. Barnabas Hospital, Newark City Hospital, Babies' Hospital and St. Michael's Hospital; aged 49; died, November 14, in Glen Ridge, of carcinoma of the pancreas.

Nathan Barlow ⊕ Hines, Ill.; Northwestern University School of Medicine, Chicago, 1902; since 1919 connected with the U. S. Veterans' Bureau; aged 54; chief of the medical staff of the Edward Hines, Jr., Hospital, where he died, November 24, of carcinoma of the pancreas.

Samuel Davis Wall ⊕ Port Arthur, Texas; University of the South Medical Department, Sewanee, Tenn., 1900; secretary of the Mary Gates Memorial Hospital; aged 54; died, August 20, in a hospital at San Antonio, as the result of injuries received in an automobile accident.

Lester Curtis, Chicago; Chicago Medical College, 1870; at one time assistant professor of physiology and professor of histology at his alma mater; on the staffs of the Cook County and Mercy hospitals; aged 88; died, November 23, of cerebral embolus and organic heart disease.

John Patrick Sweeney, Seattle; Medical Department of Columbia College, New York, 1882; member of the Washington State Medical Association; past president of the King County Medical Society; aged 73; died, September 29, of cerebral hemorrhage.

Eugene Brewster French, Jr., McComb, Miss.; Medical Department of the Tulane University of Louisiana, New Orleans, 1911; member of the Mississippi State Medical Association; aged 44; died suddenly, October 10, of angina pectoris.

Aurile Roy, Brockton, Mass.; University of Montreal Faculty of Medicine, Montreal, Que., Canada, 1905; member of the Massachusetts Medical Society; aged 51; died, October 25, of carcinoma of the sigmoid with metastasis to the liver.

Jairus Addison Joy, Easthampton, Mass.; University of Pennsylvania School of Medicine, Philadelphia, 1884; formerly on the staff of the Atlantic City (N. J.) Hospital; aged 76; died, October 24, of diverticulum of the bladder and sepsis.

Seth Smith Mullin ⊕ Bath, Maine; Medical School of Maine, Portland, 1908; formerly secretary of the Sagadahoc County Medical Society; on the staff of the Bath City Hospital; aged 47; died, August 18, of chronic nephritis.

Charles Walker Albert, Parkersburg, W. Va.; University of the South Medical Department, Sewanee, Tenn., 1899; member of the West Virginia State Medical Association; aged 58; died, October 3, of cerebral hemorrhage.

Hugh William Dicken, East Jordan, Mich.; University of Michigan Medical School, Ann Arbor, 1898; formerly mayor; served during the World War; aged 54; died, in October, at a hospital at Petoskey, of streptococcic septicemia.

Mather Humphrey Neill ⊕ San Diego, Calif.; Harvard University Medical School, Boston, 1909; surgeon, U. S. Public Health Service; aged 48; died, October 26, in Pittsfield, Mass., of myocarditis and dilatation of the heart.

Walter B. Holmes, Ada, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1894; member of the Minnesota State Medical Association; aged 64; was found dead, October 27, of heart disease.

Calvin Stuart White ⊕ Portland, Ore.; University of Oregon Medical School, Portland, 1894; past president of the state board of health; served during the World War; aged 60; died, September 25, of heart disease.

Alexander A. Cunningham, Denver; Miami Medical College, Cincinnati, 1880; member of the Colorado State Medical Society; aged 73; died, October 1, in the Porter Sanitarium, of myocarditis and chronic nephritis.

Robert Lee Sutton, Orrville, Ala.; Medical Department of Columbian University, Washington, D. C., 1889; member of the Medical Association of the State of Alabama; aged 66; died, in October, of heart disease.

Alexander Campbell Farr, Bloomington, Ind. (licensed, Indiana, 1897); aged 84; died, October 13, in St. Anthony's Hospital, Terre Haute, of hypertrophy of the prostate, arteriosclerosis and cardiorenal disease.

Joseph Thomas Woof ⊕ Chicago; Jenner Medical College, Chicago, 1906; on the staff of the West Suburban Hospital, Oak Park, Ill.; aged 57; died, October 24, of coronary thrombosis and arteriosclerosis.

Albert Linscott Stanwood, Andover, Maine; Medical School of Maine, Portland, 1876; member of the Maine Medical Association; served during the World War; aged 78; died, September 29, of pneumonia.

Lucy Maria Field Wanzer ⊕ San Francisco; University of California Medical School, 1876; for many years on the staff of the Children's Hospital; aged 89; died, October 13, of arteriosclerosis and hemiplegia.

Jonas Harrison Kauffman, Minersville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1862; Civil War veteran; aged 90; died, October 2, of arteriosclerosis and fracture of the hip.

William H. Wallace, Eureka, Calif.; Medical Department of the University of the City of New York, 1878; aged 78; died, August 9, in St. Joseph's Hospital, of acute hemorrhagic pancreatitis.

David Iley Payne, Pineville, La.; Memphis (Tenn.) Hospital Medical College, 1910; member of the Louisiana State Medical Society; aged 51; died, October 9, of coronary thrombosis.

Elmer Ellsworth Williams, Syracuse, N. Y.; Medical Department of the University of the City of New York, 1889; aged 69; died, in October, at the Crouse-Irving Hospital, of carcinoma.

Reuben Brooks Rasar, Johnson City, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1915; aged 47; died, October 2, of edema of the lungs and hepatic cirrhosis.

Charles Artman Ross, Queens Village, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1906; aged 48; died, October 13, of hypertrophic cirrhosis of the liver.

William Hayden Rockwell, Jr., New York; Medical Department of Columbia College, New York, 1892; served during the World War; aged 63; died, September 22, in Paris, France.

William Ralph Sifford, Nashville, Tenn.; Medical Department, University of Tennessee, Nashville, 1894; member of the Tennessee State Medical Association; aged 67; died, September 19.

Nathalie A. Selling, San Francisco; University of California Medical School, 1894; member of the California Medical Association; aged 63; died, October 1, of carcinoma of the breast.

Columbus Jefferson Pike, Willard, Mo.; Kansas City Medical College, 1892; formerly associate judge of the Greene County court; aged 69; died, in September, of lobar pneumonia.

Edward Joseph Walsh, Washington, D. C.; University of Tennessee College of Medicine, Memphis, 1925; aged 34; died, November 13, in the Mercy Hospital, Baltimore, of pneumonia.

Frank Leslie Barkdoll, Cumberland, Md.; Southern Homeopathic Medical College, Baltimore, 1902; aged 51; was found dead in his office, September 30, of organic heart disease.

Isaiah Miley, Anderson, Ind.; College of Physicians and Surgeons, Keokuk, Iowa, 1875; member of the Indiana State Medical Association; aged 84; died, October 23, of pneumonia.

Charles S. Curry, Beatrice, Neb.; Rush Medical College, Chicago, 1900; member of the Nebraska State Medical Association; aged 57; died, September 29, following an appendectomy.

Stuart Luthy Smith, Pittsfield, Ill.; Rush Medical College, Chicago, 1919; member of the Illinois State Medical Society; aged 37; died, October 21, of an accidental gunshot wound.

Virgil A. Baker, Marion, Ill.; St. Louis College of Physicians and Surgeons, 1903; member of the Illinois State Medical Society; aged 54; died, October 28, of heart disease.

Thompson Ribelin, Elizaville, Ky.; Louisville (Ky.) Medical College, 1880; member of the Kentucky State Medical Association; aged 71; died, October 11, of heart disease.

George M. Austin, Wilmington, Ohio; Medical College of Ohio, Cincinnati, 1883; member of the Ohio State Medical Association; aged 74; died, October 25, of heart disease.

Horace Oliver Wilson, Rison, Ark.; University of Arkansas School of Medicine, Little Rock, 1910; member of the Arkansas Medical Society; aged 46; died, September 4.

A. J. Lancaster, Pisgah, Tenn. (licensed, Tennessee, 1889); member of the Tennessee State Medical Association; aged 71; died, September 14, of senile gangrene of the left foot.

Verne Artemus Mann, Howard, N. Y.; University of Buffalo School of Medicine, 1906; aged 49; died, October 3, of acute myocarditis, asthma and dilatation of the heart.

John Tifft Beckwith ⊕ Atlantic City, N. J.; Homeopathic Hospital College, Cleveland, 1885; for many years police surgeon; aged 67; died, November 17, of angina pectoris.

Arthur Joseph Forward, Madison, N. Y.; Medical Department of the University of the City of New York, 1893; health officer; aged 59; died, September 27, of heart disease.

Davis L. Shaver, Maurertown, Va.; Baltimore Medical College, 1888; member of the Medical Society of Virginia; aged 66; died suddenly, in October, of heart disease.

Edward Louis Spitzer ⊕ New York; Bellevue Hospital Medical College, New York, 1892; on the staff of the Jewish Memorial Hospital; aged 60; died, September 18.

William Phelps Robertson, Litchfield, Minn.; Detroit College of Medicine and Surgery, 1912; county coroner; aged 43; died suddenly, October 21, of angina pectoris.

Raphael Monserrat y Marzo, Manila, P. I.; University of St. Thomas College of Medicine and Surgery, Manila, 1878; aged 79; died, August 27, of diabetes mellitus.

Henry Hinman Coleman ⊕ Mount Vernon, N. Y.; University of Buffalo School of Medicine, 1881; aged 71; died, October 8, of angina pectoris and myocarditis.

Burt Luverne Shaw ⊕ Troy, N. Y.; Albany (N. Y.) Medical College, 1904; on the staffs of the Samaritan and Leonard hospitals; aged 56; died, October 11.

Joseph Ira Coleman, Durham, N. C.; College of Physicians and Surgeons, Baltimore, 1885; aged 71; died, October 21, in the Duke Hospital, of heart disease.

William Henry Knapp, Binghamton, N. Y.; Long Island College Hospital, Brooklyn, 1874; aged 81; died, November 16, of arteriosclerosis, prostatitis and cystitis.

Curry F. Douglass, Toledo, Ohio; Medical Department of Western Reserve University, Cleveland, 1881; aged 71; died, September 20, in St. Vincent's Hospital.

Lewis Smith Hall, Augusta, Kan.; Bellevue Hospital Medical College, New York, 1878; aged 74; died, October 15, in Wichita, of carcinoma of the prostate.

Martin A. Walton, White House, Tenn.; Vanderbilt University School of Medicine, Nashville, 1886; aged 65; died suddenly, October 17, of heart disease.

Samuel A. Wideman, Spartanburg, S. C.; Medical College of the State of South Carolina, Charleston, 1899; aged 59; died, October 10, of heart disease.

Prosser Elwin Clark, Portland, Ore.; Indiana University School of Medicine, Indianapolis, 1909; aged 46; died, November 10, of rheumatic endocarditis.

Ernst Friedrich Flehme ⊕ Spokane, Wash.; University of Kiel, Germany, 1918; aged 38; died, October 19, in Frankfurt, Germany, of tumor of the kidney.

Henry A. Shurtleff, Marshall, Mich.; University of Michigan Medical School, Ann Arbor, 1879; aged 73; died, October 11, of cerebral hemorrhage.

James John Hoban ⊕ Lowell, Mass.; Jefferson Medical College of Philadelphia, 1907; aged 47; died, September 6, of neoplasm of the spinal cord.

Walter B. Hamby, Atlanta, Ga.; Atlanta Medical College, 1888; aged 64; died suddenly, November 6, in Winter Haven, Fla., of angina pectoris.

Thomas Walter Wood, Deason, Tenn.; University of Nashville Medical Department, 1870; Confederate veteran; aged 95; died, September 21.

Archibald J. Fulton, Long Beach, Calif.; Jefferson Medical College of Philadelphia, 1874; aged 84; died, September 10, of cerebral hemorrhage.

William A. Chamberlin, Waseca, Minn.; Rush Medical College, Chicago, 1882; also a druggist; aged 74; died suddenly, September 27.

Julia Holmes Smith, Chicago; Chicago Homeopathic Medical College, 1877; aged 91; died, November 10, in Winnetka, Ill., of myocarditis.

Charles A. Smith, Brooklyn; Long Island College Hospital, Brooklyn, 1891; aged 72; died, October 20, of acute dilatation of the heart.

Henry Hubert Powell, Stantonsburg, N. C.; Medical College of Virginia, Richmond, 1911; aged 44; died, October 14, of heart disease.

John C. Shepherd, New York; Medical Department of the University of the City of New York, 1891; aged 69; died, September 22.

Daniel R. Rogers ⊕ Ragan, Neb.; Jefferson Medical College of Philadelphia, 1880; aged 75; died, October 7, of appendicitis.

Preston Lee Hooper ⊕ Fort Worth, Texas; Memphis (Tenn.) Hospital Medical College, 1896; aged 59; died, September 16.

Thomas J. Hall, Caborn, Ind.; Cincinnati College of Medicine and Surgery, 1892; aged 68; died, October 4, of heart disease.

Alois Maria Renner ⊕ New York, Bohemian University of Prague, Austria, 1895; aged 63; died, in October, of heart disease.

Royse Davis, Decker, Ind.; Louisville (Ky.) Medical College, 1874; aged 82; died, October 29, of paralysis of the larynx.

Richard Ellsworth Townsend, New York; New York Homeopathic Medical College, 1882; aged 72; died, September 19.

Frank L. Wilcox ⊕ Walker, Minn.; Rush Medical College, Chicago, 1900; aged 53; was found dead in his office, August 29.

Abner George Downer, De Witt, N. Y.; New York Homeopathic Medical College, 1882; aged 74; died, October 25.

Mary L. Edwards, New York; New York Medical College and Hospital for Women, 1890; aged 70; died, September 3.

Warren A. Kitchen, New Market, Iowa; Homeopathic Hospital College, Cleveland, 1890; aged 67; died, September 23.

Jesse Edward Martin, La Center, Ky.; St. Louis College of Physicians and Surgeons, 1896; aged 61; died, September 16.

Peter J. Stammer, Victoria, Texas; Homeopathic Hospital College, Cleveland, 1880; aged 78; died, September 13.

George Lewis Lininger ⊕ Frostburg, Md.; Baltimore Medical College, 1902; aged 57; died, September 22.

Ralph Elmergreen, Milwaukee; Baltimore Medical College, 1892; aged 60; died, September 15, of heart disease.

John Hunter, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1875; aged 79; died, July 19.

John W. Dunlop, Clare, Mich. (licensed, Michigan, 1900); aged 73; died in October, of uremia.

Limitation of Manufacture of Narcotic Drugs

A conference of the government representatives of countries manufacturing dangerous narcotic drugs has sat in London for a fortnight. A report is being submitted to the British government, which convened the conference, for communication to the governments represented and to the League of Nations. A scheme for the limitation of the world manufacture of these drugs was set on foot by the assembly of the league in September, 1929, and will, it is hoped, be completed by adoption of an international agreement at the general conference to be held at Geneva in May. The main business before the London conference was to consider the proportions in which the world manufacture, when limited to the amount required for the world's medical and scientific needs on the basis of the estimates to be supplied by each country, should be distributed among the manufacturing countries and, secondly, the arrangements to be made to insure the due distribution of the drugs in the consuming countries. As regards the quotas for the manufacturing countries, the conference was not able to complete its investigations, but a provisional arrangement was reached as regards the production of cocaine. As regards morphine and its derivatives, the question is to be considered by representatives of the governments concerned with a view to an agreement before the meeting of the opium advisory committee of the league in January. The scheme of the conference leaves unaffected manufacturing countries that do not export drugs to an appreciable extent, such as the United States and Russia. At present the scheme does not cover either Japan or Turkey, both of which have reserved their decision as regards the scheme. A reservation was also made by the soviet government, which considered that the plan on which the league has been working was too narrow and should have included limitation of the production of the raw material (opium and the coca leaf) from which the drugs are manufactured.

Employment of Physicians by the Government

Evidence was given before the government commission of the civil service as regards the employment of physicians by the government. Dr. Thomas Carnwarth, representing the medical staff association of the ministry of health, pointed out that there had been an important change in the economic position of the medical profession, which had an inevitable effect on the payments that public authorities had to make for medical services. This was due to two causes. Under the national health insurance act, medical attendances per annum had been doubled as compared with 1912; secondly, the increase of the practice of preventive medicine had its effect. On the other hand, the supply of physicians in proportion to the population had declined. Hence public authorities had to offer higher salaries to attract physicians of the same standard of attainments. It was no use for the government to offer a middle-aged man a salary half of what could be earned by a younger man in practice. With regard to women physicians, he doubted whether the removal of the marriage bar (the loss of their appointment on marriage) would improve the quality of women physicians seeking entry to the government service.

A Trap for the Tsetse Fly

Mr. Harris, government entomologist, who has been investigating in the Zululand game reserve methods for the control of nagana, the tsetse-borne cattle disease, gave a demonstration before leading entomologists of his recently devised tsetse trap. He satisfied himself that the tsetse fly hunted entirely by sight. He found that it was attracted to roughly shaped dummy animals, that it usually attached itself to the belly, and that it reacted to contrasts of light and shade. The trap consists of a wooden frame on legs, covered with hessian cloth except at the bottom, and having a gauze trap at the top. It is shaped sufficiently like a living animal to attract the fly. Swooping toward the lower part of the trap, the fly comes within the hessian walls and, attracted by the light coming through the gauze above enters the trap. For the demonstration eighteen traps were set and at the end of the day were found to contain 1,393 flies, of which 942 were females. A most effective demonstration was the release of a number of flies from the trap, practically all of which found their way into it again. As the fly is not a prolific breeder, it is considered that an adequate number of traps would make marked difference in the fly population of Zululand.

An Archbishop on Birth Control

The pronouncement on birth control in the encyclical letter of the seventh Lambeth conference of the archbisphops and bishops of the Church of England was reported in THE JOURNAL, September 20, page 874, and the criticisms to which it gave rise. The extent to which the subject has become prominent is shown by the fact that at the convocation of Canterbury of the Church of England, just held, the Archbishop of Canterbury returned to the subject. He said that what was loosely called birth control had unfortunately attracted a large share of attention of the public mind. He complained that the pronouncement of the Lambeth conference had been misrepresented. It was open to the conference to ignore the whole subject, but that would have been impossible in the presence of a growing almost revolutionary change in the customs of married life throughout the world, causing a fall of 50 per cent of the world's birth rate. The great majority of the bishops approached the matter with a strong prejudice against any artificial means of controlling the birth of children, but they could not divest themselves of their sense of responsibility. The conference declared that it was wrong to enter the marriage state with the deliberate intention of avoiding parenthood, but it was compelled to recognize that in certain circumstances there might be a moral obligation to control the number and spacing of children—when birth would involve great danger to the mother, when the means available might make it impossible to provide for the rearing of another child, or when the mother might be prematurely exhausted and an additional child render her incapable of doing her duty to the existing family. The resolution of the conference said that in such circumstances the primary and obvious method was to abstain from intercourse. But it was also universally admitted that intercourse had a value of its own whereby married love was enhanced and its character strengthened and that complete abstinence might induce nervous disorders. In such exceptional cases was the artificial avoidance of conception sinful? There was no clear guidance on the point in the New Testament. The conference was therefore unable to condemn artificial methods in themselves as sinful, but insisted that their use was permissible only in exceptional cases. It condemned their use from motives of selfishness, luxury or mere convenience and asserted their absolute sinfulness apart from the married state.

Dr. Chevalier Jackson in London

Dr. Chevalier Jackson of Philadelphia delivered a lecture on suppurative disease of the lungs to the Royal Society of Medicine. The large lecture hall was overfilled by an appreciative audience. The lecture was illustrated by lantern slides and drawings on the blackboard in colored chalks, which were executed by Dr. Jackson with such skill as to excite admiration. Lord Moynihan, in proposing a vote of thanks, said that Dr. Jackson's skill with the pencil reminded him of the great

Giotto of the Italian renaissance, who sent as his card to the Pope a perfect circle drawn by a free sweep of the brush from the elbow. The president and council of the section of laryngology of the society gave a dinner in honor of Dr. Jackson. The president, Mr. Frank A. Rose, in proposing his health, suggested that he would not be remembered in future generations so much for his success in operating on the larynx for carcinoma or for his dexterity in removing foreign bodies as he would be compared to Elias Howe, who invented the sewing machine. Howe showed the world that the eye of a needle ought to be at its point and Jackson taught it to place the light of a bronchoscope at its tip. Dr. Jackson, in reply, referred to his father, who was born 100 years ago at Hull and sailed to the United States, never to return to England. He felt how this splendid welcome would have delighted him. It had been suggested that he might speak on the making of a bronchoscopist but that a bronchoscopist was born, not made.

PARIS

Fund for Promotion of Science, Literature and Art

The French minister of public instruction has decided on the creation of a national fund for the assistance of intellectual workers. Its purpose will be to supply financial aid for the carrying on of disinterested scientific researches, to furnish funds to laboratories or to create laboratories, and to accord grants or loans to scientists or aid in old age to themselves and their families. The funds will be furnished by government grants, public subscriptions and donations by large industrial, commercial and banking establishments. The fund will be entirely independent of the ministry and will be free from political interference. It will be administered by a council the members of which will be appointed by the minister and will be chosen from among eminent persons and representatives of all important educational bodies, of universities or otherwise, and of academies.

Intravenous Injections of Sodium Salicylate in Neuropsychopathic States

Dr. Targowla, physician to the Hôpitaux de Paris, has published a survey of intravenous injections of sodium salicylate in neuropsychopathic states. As a result of his experience over four years, he holds that, in a great number of psychoses, particularly acute psychoses, in which the cerebral disorder was regarded as purely psychologic, there is a toxic, infectious substratum, referable to encephalitis. He classifies such neuroses under the name of psycho-encephalites (March, 1928), having in mind not only such states as acute delirium, acute mental confusion, certain grave forms of the Korsakov syndrome, and the like, of which the organic nature and the lesions have long been known, but also essential psychoses, "without pathologic anatomy," according to the expression of Mr. Maurice de Fleury, such as anxiety neurosis, polymorphous delirium and chronic hallucinatory psychoses. This conception led him to practical results of great interest; for to these diseases mentioned, hitherto all too often rebellious to treatment, a new treatment can now be applied (depending on the infection), which gives excellent results. The new treatment consists in intravenous injections of sodium salicylate, reinforced sometimes by methenamine dissolved in serum containing dextrose, in order not to injure the walls of the vein. He secured good results in 60 per cent of the cases. The treatment brings about remarkable sedation in persons suffering from mental excitement. If the treatment is stopped too soon, the mental excitement reappears immediately, and disappears when the treatment is resumed. Its specific action is, therefore, beyond doubt. The Targowla method has been employed in Brazil by Pedro Rosa, Jacintho Godoy and others. They confirm its value and report 70 per cent of practical results. It is especially in states mistakenly termed neurasthenic, in mental confusion, mania, acute delirious states and puerperal insanity that the proportion of good results is highest; the results are, however, uncertain in chronic psychic disorders. Targowla stresses the practical character of the method, which has enabled him to treat ambulatorily, and in their homes, patients who, because of their noisy and violent reactions and their ideas of suicide, would soon have been confined in an institution. The results have been brought out especially in periodic psychoses, in which there was an opportunity of making comparisons of the course in the several attacks. Patients otherwise compelled to spend long periods in an institution may be cared for at an ordinary hospital or at home, by their family physician, and in most cases will find their mental condition vastly improved.

The Centenary of a Medical Journal

The *Journal de médecine et de chirurgie practique*, founded by Just-Lucas Championnière, Jan. 8, 1830, celebrated recently its centenary. It is the next to the oldest medical journal published in France, the oldest being the *Gazette des hôpitaux*, founded in 1817. In 1874, following the death of the father, the management was taken over by the sons, Just-Lucas Championnière and Paul-Lucas Championnière. The former was an eminent surgeon, who introduced in France the Lister method after going to London to study its operation on the ground. He died in 1913, surgeon to the hospitals and member of the institute, universally esteemed for the integrity of his character. On the death of the second brother in 1918, his son, Paul Henri Lucas Championnière, succeeded him, but he died in 1922, having been killed in an automobile accident. His cousin, Just, a son of Paul, is the present manager. It is rather unusual for the management of a medical journal to be kept in the same family for a hundred years. In honor of the occasion, the management gave a banquet for the principal members of the French medical press and also published a centennial number containing selected articles by eminent men: "Tradition and Progress," by Professor Chauffard; "The Surgical Work of Lucas Championnière," Professor Quénu; "Some Reflections on Appendicitis over a Period of Fifty Years," Professor Roux of Lausanne; "Traumatic Rupture of the Duodenum," Professor Giordano of Venice; "The Medical Treatment of Inguinal Hernia and the Pioneer Work of Lucas Championnière," Professor Forgue of Montpellier; "The Digestive Manifestations of Oxalemia," Professor Loeper and M. R. Deglos, and an article by Professor Leriche of Strasbourg on "Isolation of the Mesenteric Artery at the Beginning of Gastrectomy in the Presence of Cancer."

Death of Dr. Henri Delagénière

The death of Dr. Henri Delagénière at the age of 73 is announced. He was born at Angers and came to Paris to complete his studies in medicine, under the direction of Monod, Lucas Championnière and, more particularly, Terrier, of whom he was the favorite pupil. He was one of the first of the eminent surgeons, trained in Paris, who decided to renounce a brilliant future in the capital and to settle in the provinces and found there surgical centers, which were totally lacking other than in Lyons and Bordeaux. He established himself in Mans and created there a magnificent clinic. He founded there also the *Archives provinciales de chirurgie*. He was the author of many important works. They concern abdominal total hysterectomy, cholecysto-enterostomy, and surgery of the lung. He introduced, during the war, a method for osteoperiosteal grafts that has become classic. In 1910, he was president of the Congress of Surgery. On the day of the opening of the Société de chirurgie, Professor Gosset delivered a beautiful eulogy in his memory.

BELGIUM

(From Our Regular Correspondent)

Nov. 4, 1930.

The Brussels Medical Convention

The Brussels medical convention, the so-called Journées médicales, was an unprecedented success this year, because of the nature of the ceremonies and because of the number and importance of the papers presented by authorities from every country. Minister Baels opened the inaugural session in the presence of the king and the queen, and in his presidential address brought out the beneficial results of preventive medicine. Professor Bordet and Prof. J. L. Faure delivered inspiring addresses, the former discussing prophylactic and therapeutic medicine and the latter the progress of surgery.

A NEW CONCEPTION OF ANEMIA

Dr. Casimir Funck of Warsaw, who presented a paper on "A New Conception of Anemia," reported experiments on rats weighing at least 150 Gm. The rat weighing less than 50 Gm. is always anemic. This anemia of growth disappears when animals attain a weight of 150 Gm. Daily he injects a dose of antianemic substance, calf's liver and yeast, in a pure state at first, then treated successively with various substances, such as lead acetate, alcohol and trinitrophenol. Every two days, he makes a cell count on the blood taken from the end of the tail. It is found that yeast and liver, administered in rather heavy doses, cause at first a drop in the red corpuscles, which is followed by a slow increase. If these substances are treated successively with lead acetate, alcohol and trinitrophenol, and each time the precipitate and the filtrate obtained are injected, the precipitate causes a drop in the cell count, whereas the filtrate brings about an increase in the number of red blood cells. Mercury picrate, acting on the substances thus transformed, produces then a new filtrate, the action of which is complex, being expressed by a curve with a double turn. The author concludes that there must be two antagonistic substances in liver and yeast, one of which causes anemia while the other combats it. If a process can be discovered for the isolation of the antianemic substance from this compound, the treatment of anemias will have taken a step forward.

INCIPIENT DIETARY DEFICIENCY IN THE CHILD

Prof. Georges Mouriquand of Lyons dealt with the topic of incipient dietary deficiency in the child. Whereas the characteristic manifestations of dietary deficiency as observed in rickets, xerophthalmia, beriberi and scurvy are rare, incipient states of dietary deficiency are frequent. In rickets, long before the clinical and roentgenographic signs appear there are disturbances of calcium and phosphorus metabolism. The clinical ocular lesions of xerophthalmia are preceded by microscopic lesions distinguishable with the Gullstrand ocular microscope. Scurvy is rare, though prescurvy is frequent: retarded gait, asthenia and, more particularly, pallor and anemia, conditions that recede rapidly with the use of fluids rich in vitamin C. The researches of the author have enabled him to determine a number of factors that cause the organism to pass from a state of incipient dietary deficiency to a state of evident dietary deficiency: (1) the unbalanced nature of the diet (in addition to the deficiency in vitamin C); (2) augmentation of nutritional activity (by the administration of thyroid extract). It has been found that a relative inanition, brought about by means of a defective diet, is not favorable to the evolution of typical scurvy, which develops rather when the diet is improved. For scurvy to develop, *the child must be in a state of sufficient nutrition.* In general practice—especially in children—one encounters more frequently the complex that the author terms incipient dietary deficiency. Children on an artificial diet are in a state of latent disequilibrium; the slightest cause may bring about a condition of marked deficiency.

SINISTROSIS

Dr. Julliard of Geneva, after recalling Brissaud's definition of sinistrosis, reported the results of his experiences in Switzerland as to the various ways of handling these cases of neurosis arising out of claims for compensation. The determining cause of this disorder, according to Julliard, is the law pertaining to occupational accidents, which causes the injured man to conjure up a vision of the pecuniary gain that he might draw from his accident. The best way to cure sinistrosis is to place the subject in a situation in which he can claim nothing and hope for nothing. Therefore, he should either be allowed a single lump sum by way of complete compensation or he should be refused categorically all indemnity, since sinistrosis is not a compensable disease, and should thus be compelled to resume his work. While the allocation of a certain sum of money may be more humane, it has the great disadvantage, says Julliard, of establishing a bad precedent—of producing contagion, so to speak, when prophylaxis is indicated. The speaker recommended, therefore, the categorical refusal of all compensation, and, by citing a number of examples, endeavored to refute the objections urged against his system. Julliard began, seven years ago, a campaign against the granting of compensation in cases of "sinistrosis," and he states that the results have been entirely satisfactory.

THE NEW CYTOLOGY

Dr. Carrel of New York, in his paper on "The New Cytology," brought out that the present-day conception of cytology, from the standpoint of the technic of the science, is essentially morphologic. An interesting point of view at present, however, is the study of cell development as a time function and from the angle of its physiologic mechanism. Such study has of late become possible through the cultivation of tissues, which notably has enabled the researcher to follow the modifications effected in the vitality of the cells by the changes in their external surroundings. These results have been secured only by improvements in technic, whereby it has become possible to study cytologically tissue fragments in process of growth. The essential requirement for the conservation of tissue cultures is to maintain their milieu constant. Under such conditions, they can be preserved for a considerable length of time. Carrel stated that he had cultures of connective tissue of chicken embryos dating back eighteen years. Some remarkable results have already been secured by the observation and chemical study of the milieu of cultures of various tissues; notably, various types of fibroblasts. These elements, similar in their histologic structure, have been found to vary in the morphology of their cultivation, in their growth activity and in their diverse nutrition. The pure cultures of tissues are secured either by the selection of tissue fragments under the binocular microscope or by chemical action and the suppression, from choice, of certain kinds of tissue. Thus, some knowledge of the fundamental nature of malignity in certain tumors has been secured—which corresponds to certain profound modifications in the mode of nutrition of the cultures of malignant tissues studied. Interesting facts have been learned also from the action of certain plasmas on the cultures in relation to senility.

PRESENT-DAY TENDENCIES IN OBSTETRICS

Prof. Maurice Brouha of Liége presented a paper on "Present-Day Tendencies in Obstetrics." After calling to mind the period when obstetrics was regarded as the "poor relative" of surgery and medicine, he painted a picture of its present state. The obstetric clinic has been greatly enriched by laboratory discoveries; by the progress of surgery and the contributions of modern sociology. Of the most frequent *morbid* entities, puerperal infection has imposed a severe technic, which finds its application best assured in a surgical milieu, which permits a thorough training in the principles of asepsis and antisepsis; also the development of the surgical temperament, so indispensable for the obstetrician. Cases of narrow pelvis give the best proof of his obstetric sense. The tendency to surgery is encountered with respect to operations for placenta praevia, 10 per cent of which are fatal for the mother and 50 per cent for the unborn child; in view of the hazards of the operation, it would be unwise to resort to a waiting policy other than in a hospital or clinic. In eclampsia also modern tendencies are observable. The older method of forcing birth by natural means is giving way to expectant and medical methods, and even to surgical methods, when the life of the child is at stake.

It is evident that the obstetrician of today must possess the highest medical and surgical ability, such as can be acquired *only by a long graduate preparation under select conditions.*

At this time, when the newly introduced social system is planning to cover the risks of maternity as well as of disease, the interesting question arises as to who shall bear the chief responsibility and as to what will be the rôle, in the future, of *the midwife, the general practitioner and the obstetrician.*

THE TUBERCULOUS ULTRAVIRUS AND BACILLARY INFECTION

Professor Calmette of Paris took as his subject "The Tuberculous Ultravirus and Bacillary Infection." In addition to permanent ultraviruses, there are others that are in reality only a phase in the morphologic evolution of a micro-organism; for instance, the virus of pleuropneumonia in bovines. Fontes of Rio de Janeiro was the first (1910) to observe that pus from tuberculous lesions in man, when filtered and inoculated into the guinea-pig, causes a slight swelling of the lymph glands, which are found to contain a few tubercle bacilli. The publication of this experiment attracted little attention. Twelve years later, in 1922, Vaudremer discovered, in cultures of tubercle bacilli grown in a poor medium, certain granular forms and secured, through filtration of these cultures, a fluid that, inoculated into the guinea-pig, produced a glandular swelling, and later small caseous masses, some of which contained acid-fast granulations which, when implanted in a favorable culture medium, yield normal bacillary forms. No others, however, were able to verify this experiment.

In 1923, Valtis, working in the Calmette laboratory, took up the experiments of Fontes and confirmed them. The inoculation into the guinea-pig of a filtrate of tuberculous material produces an atypical tuberculosis. On the tenth day, a slight swelling of the lymph glands is observable, and these are found to contain rare acid-fast bacillary elements. Reinoculation in series of animals of the content of these glands often produces, after six or seven passages, typical tuberculous lesions containing genuine tubercle bacilli. This atypical tuberculosis of the guinea-pig can be produced with the filtrate of young cultures or of pathologic products the tuberculous nature of which was not fully demonstrated. The discovery of the tuberculous ultravirus has had important consequences for the study of alleged hereditary tuberculosis. If one inoculates such filtrates into gravid guinea-pigs, the organism of the young offspring is found to contain the ultravirus, which must have passed through *the placenta. Likewise, in the human species, from 9 to 12 per* cent of the children born of tuberculous mothers die during the first weeks of life, presenting a syndrome characterized by progressive denutrition, without visible lesions at necropsy. The inoculation into the guinea-pig of the product derived from their lymph glands reveals the presence of the tuberculous ultravirus. Their deaths appear to be due to an intoxication that accompanies the presence of the ultravirus and that damages in some way the nervous tissue.

After long research, Calmette has succeeded in cultivating the ultravirus on a special culture medium. In this culture, after the lapse of a few hours, fine non-acid-fast granulations are found; then larger granules, some of which are acidophilous, and finally true bacillary forms appear. Intravenous inoculation into the rabbit of such a culture ten days old causes death within forty-eight hours, with paralysis of the posterior or anterior limbs. The culture contains, therefore, a thermolabile toxin that does not appear until the tenth day, the time the granulations disappear, and seeming to be produced by the lysis of these granules. It is probable that the death of the new-born, since it presents the syndrome of progressive denutrition, is due to this special toxin that forms at a given moment in the maternal organism.

These conceptions *necessitate a revision of our ideas in regard* to the pathogenesis and evolution of tuberculosis. The tubercle bacillus is only a terminal form of the evolution of the tuberculous virus. There are doubtless pathologic conditions due exclusively to the ultravirus. They might possibly be well termed "prebacillary granulemias," for most of them may lead to typical tuberculosis. Those conditions that are due to the tubercle bacillus should be termed "bacilloses." Between these two groups, there is a place for diseases in which the bacilli do not appear until the terminal phase, and then only in small numbers.

A Movement to Aid Diabetic Patients

Among the principal changes that the discovery of insulin has brought is the fact that a much larger percentage of diabetic patients regain their capacity for work. A still greater proportion could regain such capacity if they received proper care. The possibility of recovering fair physical health and almost normal working performance exists today for a much larger number among patients with mild diabetes than formerly. More attention should be given, therefore, to the social side of treatment. But it is evident that far less is being accomplished with diabetic patients than should be attained in view of the means now at the disposal of physicians. It is astonishing how few diabetic patients after dismissal from the hospital keep themselves in metabolic equilibrium, succeed in finding employment, and are able to hold a position any length of time. For these medical and social reasons, Professor Katsch, internist, of Greifswald, was instrumental in having a special convalescents' home for diabetic patients opened in Garz auf Rügen, Pomerania, September 17. Diabetic patients who are out of immediate danger can remain in the home shorter or longer periods, depending on the indications, and while there will be under careful guidance with respect to their metabolism and will receive individual attention in the quantitative and qualitative apportionment of their food. Through individual occupational therapy they become familiar with modes of employment that correspond to their physical capacity. At the same time, their power of performance is tested and classified in connection with a constant control of their metabolism. The correct diet adapted to the individual and suited to the work performance is determined, which can be done more easily in the home than in the hospital. The patient receives not only instruction as to correct dietetic behavior but also as to the extent that he can safely work. The careful control of metabolism and diet, carried out over a period of several weeks or months, leads, at the same time, to a restoration and strengthening of the defective functions, to an improvement of the status of metabolism, and to an increase in the capacity for work. In order that the patients, after their dismissal from the home, may be able to maintain themselves permanently in the struggle for existence, an individual vocational guidance bureau and occupational aid have been established in which endeavor several official bodies cooperate. The home for diabetic patients is a public charitable institution, comprising a residence with forty tastefully furnished rooms, an administration building, stables, workshops, a landscape garden and an agricultural plant. It can house comfortably sixty patients.

The work of the diet kitchen is facilitated by the fact that the cuisine is planned almost entirely for patients with diabetes. Even a number of the personnel have the disease. Instruction in the dietetic preparation of food for diabetic patients, especially instruction for diabetic women and for the wives of diabetic men, is provided. The introduction of occupational therapy gives the institution an especially modern character. Occupational therapy is under the intimate control of physicians.

Roentgenologic Demonstration of Liver and Spleen

Addressing the Berliner Medizinische Gesellschaft recently, Dr. Radt, on the staff of the Moabit Hospital, discussed "Roentgenologic Demonstration of Liver and Spleen with the Aid of a New Contrast Medium." By the intravenous injection of a thorium dioxide solution, which is deposited in the reticulo-endothelial apparatus, Radt succeeded in bringing out clearly in the roentgenogram both the liver and the spleen as organs presenting uniform shadows. The diagnosis of cancer metastases, which appear as figures of lessened density, can be confirmed in this manner. Experimental animals and human beings suffer no evil effects from the use of this contrast medium. The roentgenograms presented were excellent and were highly approved by the assembly.

Newer Methods of Immunization Against Diphtheria

Before the Berliner Medizinische Gesellschaft, Professor Kolle, the director of the Institut für experimentelle Therapie in Frankfort-on-Main, spoke recently on "Newer Researches on Immunization Against Diphtheria and Methods of Testing and Determining the Value of Diphtheria Immunization Substances." The frequent failure of serum therapy in severe diphtheria, even after early treatment with highly potent antitoxin units, is due, not to the unsuitable nature of the serum but to the fact that the various diphtheria strains produce toxins of varying potency; other reasons are the mixed nature of the infection and the lymphatic constitution of the patient, to be regarded as labile. Therefore, trials with active immunization have been made and mixtures of toxin and antitoxin have been prepared. In connection with his work of receiving the government's methods of testing vaccination substances, Kolle showed by numerous experiments that the vaccines employed at present vary widely in quality. When used for immunization purposes or therapeutically the effects expected are not always realized. The formaldehyde vaccines have given the best results (toxoid). Kolle has prepared a new vaccine, which has shown a high degree of efficacy in prophylactic and therapeutic trials. The intramuscular injection of the vaccine is said to be devoid of danger. That a negative phase occurs after inoculation, with an increased disposition toward the disease, is denied, as it cannot be demonstrated by animal experimentation. The introduction of general vaccination against diphtheria is recommended to the medical boards.

The B C G Vaccine—Pro and Con

At present, the federal bureau of health is testing the theory of the Bulgarian physician Petrov to the effect that the Calmette bacilli have a tendency, under certain circumstances, to become virulent again. That is said to be an explanation for the Lübeck accidents. In the *Deutsche medizinische Wochenschrift,* Prof. R. Kraus of the State Bacteriologic Institute in Chile reports that it has been decided there to interrupt the use of the B C G vaccine for the time being. A child that was treated with the vaccine a week after birth died a year and a half later; the necropsy observations were "tuberculosis." The inoculation of rabbits and guinea-pigs with a culture prepared from material from the lung produced tuberculosis. The causative agent was found to be a strain of bovine tubercle bacilli, and, as the child had received no raw milk, Kraus assumes that the condition was caused by a strain of the Calmette bacillus that had regained its virulence.

Kraus called attention to a research of Hutyra, who reports that in winter a generalized tuberculosis appears in young guinea-pigs inoculated with the Calmette vaccine. Tubercle bacilli cultures can be secured from them that have pathogenic qualities. Hutyra has been unable to make in summer the same observations, so that he assumes that possibly intercurrent infections may cause an increase of virulence, which was later confirmed experimentally by Hormaeche and Mackinnon of Montevideo. Further interesting experiments of Hutyra and Hormaeche have shown that a Calmette strain with increased pathogenicity was found to be especially pathogenic for guinea-pigs, less pathogenic for rabbits and nonpathogenic for cattle.

In a reply, which is published in the same issue of the journal, Calmette calls attention to the fact that the isolated experiments of Hutyra, Hormaeche and Petrov have not been confirmed by anybody. As to the child who had died, who is said to have received no raw milk, Professor Fontecilla and R. Debre established that there was no certainty that the child had received no raw milk, and that, furthermore, the nurse that cared for the child has tuberculosis of the lungs and the kidneys. It is therefore possible that the child (which, moreover, died from pneumonia following whooping cough) became infected through the nurse, and that the tuberculous changes in the lung, found at necropsy, would not have spread if the whooping cough had not developed.

Merger for the Promotion of German Science

In the plenary assembly hall of the Herrenhaus, the former upper chamber of Prussia, the Notgemeinschaft der Deutschen Wissenschaft, now called the "Deutsche Gemeinschaft zur Erhaltung und Förderung der Forschung," celebrated recently its tenth anniversary. The federal government and the Stifterverband, during the difficult years of the postwar period, supported the Notgemeinschaft and thus made possible the continued existence of German science. Schmidt-Ott, the chairman and formerly Prussian minister of public education, described the principal aspects of its work. Even in the most critical period, the mistake was not made of supporting only especially useful branches of research; science was treated as an indivisible whole, The principal objective was, of course, the support of such researches as would promote especially the economic welfare, the public health and the public weal. The Notgemeinschaft has been governed in its activities by considerations of absolute and most strict reality. It is greatly to be regretted that, at the present critical period in the progress of German science, when the pioneer work of technical and scientific research is indispensable for the advancement of economic conditions, a decrease in the appropriations for the Notgemeinschaft is contemplated. Recognition of the fact that funds spent for research constitute just so much wisely invested capital, which will bring returns through the improvement of economic conditions, must penetrate more deeply into the consciousness of the general public.

Prof. Dr. Straub, pharmacologist, of Munich, spoke on "Vitamins, Hormones and Public Health." He said, in closing, that the public health will not derive the full advantages from modern research on vitamins and hormones until these substances become available in large quantities for the masses. That will require the discovery of inexpensive original material from which these substances may be obtained, and possibly their synthetic production. The vitamin that possesses such high therapeutic value in rickets can now be secured from yeast, while the hormone of the thyroid gland can be produced synthetically. Here lies the further task of the two sciences chemistry and medicine working hand in hand.

There followed an address by Professor Frings of Leipzig on "Aus dem Forschungsgebiet der Volkskunde." In conclusion, Professor Konen of Bonn spoke on "Aus dem Grenzgebiet von Technik and Forschung," in which he emphasized the important work of the Notgemeinschaft in determining the causes of mine disasters.

Correspondence

POISON IVY

To the Editor:—Having spent considerable time on the investigation of the active principle of various poisonous plants of the rhus family, including poison ivy, poison oak, poison sumach and Japanese sumach, I was greatly interested in the article by Dr. Paul D. Lamson on benzoyl peroxide in the treatment of poison ivy intoxication (The Journal, August 30, p. 663). The active principle of all poisonous rhus is practically the same. In physical appearance it resembles a fixed oil, but unlike the oils it does not yield glycerin on saponification. Its properties more nearly resemble an acid resin. It is very adhesive and it is almost impossible to remove it from the skin or clothing with soap and water. Hence it is easily conveyed from one part of the body to another. This has led many to believe that it spreads, and also that the serum is poisonous, as suggested by Dr. Lamson. This is not the case. If the surface which has been in contact with the poison is thoroughly washed with alcohol, kerosene, ether or gasoline, the effect of the poison will be confined to its original location. There is no danger from contact with the poison if the surface is thus washed within ten or fifteen minutes. This has been proved by numerous experiments. Though I am highly sensitive to the poison, I worked with it for months without any injurious effects.

The serum from acute cases of poisoning was applied to very sensitive tissues with negative results.

Liniments or ointments should never be applied to a poisoned surface unless it has been thoroughly washed with one of the solvents mentioned. Otherwise the poison will be dissolved and spread to the surrounding tissue.

Of the numerous methods of treatment that have been recommended for poison ivy, at least 95 per cent are of questionable value. They have been used during the last stages of the infection, and have received credit for the cure. It is to be hoped that benzoyl peroxide, recommended by Dr. Lamson, will prove an exception; but if the poison is removed before the peroxide is applied it is questionable whether an oxidizing agent is needed. Doubtless its greatest value will be in relieving the intense itching, and it may aid in drying up the lesions. Apparently its anesthetic action is more permanent than phenol, though not so rapid. A 3 or 4 per cent solution of phenol will relieve the itching in four or five minutes.

A. B. Stevens, Ph.C., Ph.D., Sc.D., Escondido, Calif.

"IS A MEAT DIET A MENACE?"

To the Editor:—In defense of the editorial entitled "Is a Meat Diet a Menace?" (The Journal, September 20, p. 866) and in reply to the criticism of Dr. Mark Falcon-Lesses (The Journal, November 8, p. 1445), it should be pointed out that the experiment of Newburgh, Falcon-Lesses and Johnston cited as proof of kidney damage really shows what extreme abuse the human body will stand with only a temporary damage resulting. The human subject used in this experiment may be considered to have been an average sized man doing the usual nonstrenuous activities of a member of a laboratory staff. Yet Newburgh, Falcon-Lesses and Johnston fed this subject a diet containing 4,177 calories and 327 Gm. of animal protein daily. A truly Gargantuan diet! Furthermore, in the preliminary control period, what was termed a normal number of casts appeared in the urine of the subject. The word "normal" in this case must be interpreted to mean "that number of casts which the clinician considers insufficient to warrant treatment." This normal number can logically be considered to indicate a mild existing kidney weakness. In spite of this and in spite of the high calory diet (about 50 per cent more than an average adult office worker needs) the subject showed no permanent damage since the urines promptly returned to the prediet condition when the diet was reduced to a normal one.

In regard to the relevancy of the experiments on laboratory animals conducted by Newburgh and his colleagues, it should again be pointed out that high protein experiments with rabbits are worthless. Concerning the rat experiments which are cited to show that high protein diets are harmful, Newburgh's work has been confirmed by Polvogt, McCollum and Simmonds (*Bull. Johns Hopkins Hosp.* **34:**168 [May] 1923), Evans and Risley (*California & West. Med.* **23:**437 [April] 1925) and Moise and Smith (*Arch. Path. & Lab. Med.* **4:**530 [Oct.] 1927). However, these results have been more than offset by the work of others who have shown no kidney damage from high protein diets when other factors were properly controlled. Among these other investigators are Drummond, Crowden and Hill (*J. Physiol.* **56:**413, 1922), Reader and Drummond (*J. Physiol.* **59:**472 [March] 1925), Osborne and Mendel (*J. Biol. Chem.* **59:**13 [Feb.] 1924; *Am. J. Physiol.* **68:**143, 1924), Osborne, Mendel, Park and Winternitz (*J. Biol. Chem.* **71:**317 [Jan.] 1927), Jackson and Riggs (*Proc. Soc. Exper. Biol. & Med.* **22:**482, 1925; *J. Biol. Chem.* **67:**101 [Jan.] 1926), MacLean, Smith and Urquhart (*Brit. J. Exper. Path.* **7:**360 [Dec.] 1926), Miller (*J. Exper. Med.* **42:**897 [Dec.] 1925), Addis and the MacKays (*J. Biol. Chem.* **71:**139 [Dec.] 1926), Kennedy (*Quart. J. Exper. Physiol.* **16:**281 [Aug.] 1926) and Anderson (*Arch. Int. Med.* **37:**297, 313 [March] 1926).

Chicago.

"CONTROLLED EXPERIMENTATION, HEMOCHROMATOSIS, AND THE ALCOHOL PROBLEM"

To the Editor:—A little over a year ago (Feb. 2, 1929) an editorial appeared in The Journal under the heading "Controlled Experimentation, Hemochromatosis, and the Alcohol Problem." In this editorial the importance of experimentation in medicine was stressed, but the absence of trained experimentalists, particularly in medicine, was deplored. The statements were made that "experiments in which animals are employed require unusual vigilance," that "two sets of animals are used as a rule, one for the experiment and another to control it," that "the neglect to employ infallible control experiments is appalling," and that "the paths to new and fruitful knowledge are so littered and encumbered with the wrecks and tragedies of defective experimentation that tracing the source of most of the advantages of modern medicine is an involved and difficult undertaking." The work of Mallory and his pupils in experimental hemachromatosis due to chronic copper poisoning (*J. M. Research* **42:**461 [Oct.-Dec.] 1921; *Arch. Int. Med.* **34:**292 [Sept.] 1924; *Am. J. Path.* **1:**117 [Jan.] 1925; *Arch. Int. Med.* **37:**336 [March] 1926) were taken as an example of such uncontrolled experimentation. This attitude was based on a paper by Flinn and Von Glahn (*J. Exper. Med.* **49:**5 [Jan.] 1929) in which the increased copper content of the tissues in human and experimental hemochromatosis, as compared with healthy tissues or tissues diseased in other ways, was denied and the statement made that the deposition of pigment could be produced in the livers of rabbits by the feeding of carrots exclusively.

This editorial seemed to me exceedingly unfair. Few experimentalists would ever assert that their published work was indisputably correct. The criticism concerned work that had been done by or under the supervision of an investigator who has carried on experimentation, particularly in relation to liver cirrhosis, for nearly forty years. Statements such as "The lesions to be described . . . are an outcome of a number of years of experimental work with various chemical reagents which might possibly be the cause of . . . alcoholic cirrhosis and hemochromatosis" and "of the other metals which form hemol compounds with hemoglobin, zinc is the only one which causes a lesion closely resembling that produced by copper," both of which appeared in the original article on the experimental work (*J. M. Research* **42**:475, 478 [Oct.-Dec.] 1921) certainly implied that the tissues of many animals, other than those fed with copper, had been carefully examined. At that time, however, my comment was withheld because of the feeling that my views were probably prejudiced because of collaboration in the experimental work.

The increased copper content in tissues from clinical cases of hemochromatosis has recently been confirmed by Oshima and Schönheimer (*Ztschr. f. physiol. Chem.* [Hoppe-Seyler's] **180**: 252 [Dec.] 1928) and increased copper content of the tissues together with pigmentation of the liver in experimental chronic copper poisoning has been reported by Oshima and Siebert (*Beitr. z. path. Anat. u. z. allg. Path.* **84**:106 [Feb.] 1930). In spite of the failure of the latter to demonstrate liver cell necrosis and increase in connective tissue of the liver, sufficient confirmation is available to warrant an editorial, "Hemochromatosis" (THE JOURNAL, October 4, p. 1022) in your columns in which the contribution of Mallory to the etiology of hemochromatosis is favorably commented on. No reference whatever is made to your previous editorial in which the same work was adversely criticized.

ROBERT N. NYE, M.D., Boston.

[COMMENT.—Dr. Nye calls attention to the fact that medical opinions change and that editorials in THE JOURNAL reflect the current point of view. When the first editorial was published, the material covered in the second editorial was not available. It is well to have the letter of Dr. Nye, which points out the way in which continued research has brought a change in the point of view of hemochromatosis. The second editorial might well have called attention to the fact that the previous view had been modified.—ED.]

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

DIFFERENTIAL DIAGNOSIS OF HEADACHE AND VOMITING IN CHILDREN

To the Editor:—A white girl, aged 8 years, perfectly well until four months ago, had a previous negative history except for scarlet fever without complications. At that time she was seized with an attack of vomiting at 5: 30 a. m. Since then the child has been having vomiting spells, which always seem to come at the same time of the morning. The child is awakened from sleep with a headache and then vomits. The vomiting is not projectile in character, and the vomitus is clear, containing mucus but no food. There is no nausea and the headache clears up after the vomiting. She vomits two or three times and then is perfectly well. Between attacks she acts normally and has no complaints. This morning she vomited and after the attack she felt a numbness in the left side of her tongue and in her left arm and leg, which passed off in a few hours. She vomits once every two weeks, at the same time, but not on the same day. She has lost about 3 pounls (1.4 Kg.) in weight. The physical examination is negative except for bilaterally equal but exaggerated knee jerks, and a left antrum which does not transilluminate as clearly as the right, but the difference is slight. Is this a case of Leyden's periodic vomiting? Are there any therapeutic suggestions outside of mental rest and nerve sedatives that you can offer?

G. H. PETTI, M.D., New York.

ANSWER.—Headache is not an uncommon complaint of sick children. Headache and vomiting may be associated in a variety of disorders. It would be superfluous to enumerate all the organic, toxic and functional conditions that might cause either or both. Recurrent nocturnal headache is a frequent expression of organic cerebral disease, especially if associated with vomiting, inequality of the pupils, strabismus, optic neuritis, irregularity of the pulse and convulsions.

Eyestrain, glaucoma and iritis are sometimes found to produce cephalalgia. Otitis media may act in the same way. Infection of the accessory sinuses may cause headache as well as vomiting. One sometimes hears children complain of headache after mild attacks of petit mal.

Chorea, rheumatism, dental caries, chronic tonsillitis and other conditions have undoubtedly been considered and excluded as etiologic factors.

Two other disorders may possibly be confirmed or excluded by an investigation of the patient during an attack. Leyden published a paper on periodic vomiting in the *Zeitschrift für klinische Medizin* in 1882. A vast literature on this subject has accumulated and the condition that he described is now known in the literature as cyclic vomiting, periodic vomiting or recurrent vomiting with acetonemia. It usually occurs in neuropathic children or in those coming from nervous parents.

In cyclic vomiting there is usually a disturbance due to anomalies in carbohydrate metabolism. The blood sugar is usually diminished and acetone bodies are excreted through the lungs and the kidneys. This disorder occurs at shorter or longer intervals, and the patients usually have an elevation of temperature, are drowsy and prostrated, and remain ill several days. It is clear that, if the urine is examined at this time for acetone bodies and the clinical course and symptoms are taken into account, the diagnosis of recurrent or cyclic vomiting could be established with little difficulty.

However, the history states that the child is first seized with headache and then vomits. Possibly this little girl is suffering from migraine, which may occur in early childhood. It has been recognized in a child 2 years of age. There may be a slight temporary pyrexia during an attack in children. There seems to be some relationship between migraine and epilepsy. It is not unlikely that in both diseases an irritation of the cortical brain substance is present in varying degree. The same thought would explain nausea and vomiting as an expression of general cerebral disturbance. Unilateral headache is the rule in migraine, though it is said that it may occur without nausea or vomiting; it has also been asserted that there are cases in which periodic attacks of nausea have occurred without headache. Heredity is an important fact to elicit in the family history. In many of the cases of migraine in children, one or both parents or some near relatives are also affected. These patients often complain of sensory disturbances in the limbs. Numbness, tingling and a sensation of pins and needles or of burning are not infrequently associated with migraine.

The history of this little girl states that she felt a numbness in the left arm and leg which passed off in a few hours. Visual disturbances are not uncommon in this disease. The visual acuity may be diminished in varying degrees during the attack. Sometimes there are temporary ocular disturbances which resemble the aura of epilepsy.

A neurotic or hysterical attack might suggest itself. As a general rule this is not a safe diagnosis to venture. Every reasonable diagnostic resource should be employed to exclude organic disease and local infection. Cyclic vomiting and migraine should be most thoughtfully considered.

In view of the difficulty of establishing a definite diagnosis, it is obvious that any suggestion about treatment should be deferred.

REMOVAL OF TATTOO MARKS

To the Editor:—I have a patient living at a distance who is quite anxious to remove some tattooing on the skin. The following directions, taken from Pocket Medical Formulary by W. E. Fitch, M.D., F. A. Davis Company, publishers, were sent to him: "A New Way of Removing Tattooing: ℞ 1900 ½. First the skin is vigorously rubbed until the outer epidermis comes off; then a paste of quicklime, just slaked, to which pulverized phosphorus (two tablespoonfuls to a pint) is added and thoroughly mixed, is applied to the tattooed surface and held by a bandage which is taken off two days later. The crust is left to dry and then fall off by itself, in about fifteen days. A second application should be made; a third is rarely necessary. Thus treated the tattooing disappears completely without the least scar." On attempting to have the formula compounded, he was told that pulverized phosphorus could not be obtained. Please tell me where pulverized phosphorus may be obtained and also your opinion of the efficacy of this formula. Please omit name.

M.D., Illinois.

ANSWER.—The removal of tattoo marks is extremely difficult and most of the methods suggested are unsatisfactory. The method with phosphorus, described in the letter, is not one widely recommended. No method would justify the claim that it removes the tattooing completely "without the least scar." The pigment in tattoo marks is too deep for that. The method for removing tattoo marks usually recommended is that with a 50 per cent solution of tannic acid to be tattooed into the surface, the method introduced by Variot in 1888. This consists essentially of tattooing with a 50 per cent solution of tannic acid and rubbing the surface with silver nitrate sticks. Dr. Marvin H. Shie has had a large experience in removing tattoo marks in the United States Public Health Service and he uses the Variot method, with a careful technic. He considers the subject of tattooing and the methods of its removal in an instructive article in The Journal (Jan. 14, 1928, p. 94).

BRONCHIAL ASTHMA

To the Editor:—A girl, aged 6, is well nourished and apparently normal in every particular, except that she has frequent attacks of bronchial asthma, especially at night. She has had it since she was 1½ years old, at which time she was given three injections of diphtheria toxin-antitoxin. Following the first injection she began to have asthma; she was much worse after the second and violently ill after the third and has had the attacks ever since. Skin tests have been made, and the substances to which she was hypersensitive have been excluded from her diet. Is there any way to desensitize this patient to overcome the bad effects of the serum which, it seems, must have been the cause of her trouble?

M.D., Indiana.

Answer.—Many allergic patients react excessively to horse serum. They are frequently spontaneously hypersensitive. This probably has little to do with the trouble at the present time. The patient is probably sensitive to some agent with which she is in constant contact. A thorough allergic study of the case should be made.

EPILEPSY A CONTRAINDICATION TO MARRIAGE

To the Editor:—A man, aged 25, has epilepsy characterized by petit mal attacks. Under phenobarbital therapy the "flashes" occur about once every four to seven days, lasting from ten to twenty seconds. Would you advise against marriage? If the patient does get married, are the chances of his children having epilepsy much greater than if both parents were normal? Can you refer me to literature on the subject?

M.D., New York.

Answer.—There is general agreement that heredity is an important factor in the etiology of true epilepsy; there is also no doubt that the children of epileptic parents are more frequently epileptic or feebleminded than are the offspring of normal parents. It seems probable, however, that the anlage to epilepsy is recessive in the mendelian sense, and for this reason when only one parent is epileptic the offspring may not show this condition, though it may appear in later generations; if both parents are epileptic it is probable that all children will be epileptic or feebleminded or both. There is also a relation between nervous diseases in the ascendants and epilepsy in the descendants, so that a mating between a person with epilepsy and one from a family with neuropathic traits, even in the absence of actual epilepsy, would also be an extremely serious risk. All textbooks on nervous diseases discuss this problem to some extent and there is a brief summary in Heredity in Nervous and Mental Disease, New York, Paul B. Hoeber, Inc., p. 258. In the latter will be found references to other articles, notably one by Snell, O.: Die Belastungsverhältnisse bei der genuinen Epilepsie (*Ztschr. f. d. ges. Neurol. u. Psychiat.* **70:**1, 1921).

TRANSIENT HEMIPLEGIA

To the Editor:—A man, aged 69, with well developed arteriosclerosis and hypertrophy of the left ventricle of the heart, suddenly became paralyzed on the entire right side one week ago, after eating a hearty breakfast. The paralysis lasted half an hour and disappeared. Since then he has had five or six similar attacks, which have lasted from ten minutes to an hour. The last attack affected the throat muscles and the speech. Sometimes the leg twitches during an attack. I am treating this as a case of threatened apoplexy.

Albert Beam, M.D., Americus, Kan.

Answer.—Transient hemiplegias and aphasias of the type described, associated with arteriosclerosis, may be compared with similar transient paralyses of spinal origin which are usually described as intermittent claudication. The exact mechanism of their production is not clearly established, but it seems probable that for some reason there is a temporary stasis of the blood, which is liable to lead to thrombosis rather than to hemorrhage. Patients may have many such attacks and escape a permanent lesion. In the management of such cases, the regimen must be that for arteriosclerosis. In view of the possibility of thrombosis, it is unwise to do anything directed toward reducing blood pressure; rather the heart needs supporting. Avoidance of strains and stresses, emotional and otherwise, with regulation of diet are the most important indications.

Virginia: Richmond, Dec. 9-12, 1930. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke, Va.

Washington: Seattle, Basic Science, Jan. 8-9, 1931. Regular, Jan. 12-13, 1931. Dir., Mr. Charles Maybury, Olympia, Wash.

Wisconsin: Milwaukee, Dec. 13, 1930. Basic Science. Sec., Prof. R. N. Bauer, 3410 Wisconsin Ave., Milwaukee, Wis. Regular, Madison, Jan. 13-15, 1931. Sec., Dr. R. E. Flynn, 315 State Bank Bldg., La Crosse, Wis.

Mississippi June Examination

Dr. F. J. Underwood, secretary of the State Board of Health of Mississippi, reports the written examination held at Jackson, June 25-27, 1930. The examination covered 12 subjects and included 96 questions. An average of 75 per cent was required to pass. Thirty-three candidates were examined, 31 of whom passed and 2 failed. The following colleges were represented:

College	Year Grad.	Per Cent
PASSED		
University of Arkansas School of Medicine	(1930)	82
Emory University School of Medicine	(1930)	86, 89
University of Illinois College of Medicine	(1930)	79,* 86,* 87*
University of Louisville School of Medicine	(1930)	85, 85
Tulane Univ. of Louisiana School of Med.	(1930)	82, 84, 88, 89, 90
Creighton University School of Medicine	(1929)	83
Jefferson Medical College	(1930)	83
University of Pennsylvania School of Medicine	(1930)	85, 89
Meharry Medical College	(1930)	81
University of Tennessee College of Medicine	(1930)	80, 82, 83, 84, 84, 85, 86, 88
Vanderbilt University School of Medicine	(1930)	83, 86, 87, 88
Dalhousie University Faculty of Medicine	(1924)	83
FAILED		
Nongraduates		36,† 66†

* This applicant has received a four year certificate and will receive an M.D. degree on completion of one year's internship in a hospital.

† These candidates were admitted to the examination by special acts of the legislature: chapter 132, House Bills 288 and 735.

Dr. Underwood also reports 12 physicians licensed through reciprocity with other states at the same meeting. The following colleges were represented:

College	Year Grad.	Reciprocity with
LICENSED BY RECIPROCITY		
University of Arkansas School of Medicine	(1905)	Louisiana
Hahnemann Medical College of Illinois	(1899) (1905)	Illinois
Northwestern University Medical School	(1928)	Missouri
Tulane University of Louisiana School of Medicine	(1923)	Alabama
	(1927) (1928, 2)	Louisiana
Jefferson Medical	(1915)	Virginia
University of Ten	1922) (1927)	Tennessee
University of Vern	(1905)	Vermont

Social Medicine and Medical Economics

THE WHITE HOUSE CONFERENCE ON CHILD HEALTH AND PROTECTION

President Hoover called together, more than a year ago, a small group to initiate the organization of a Conference on Child Health and Protection. In due time the group was enlarged until about 1,200 representative citizens from every field of child welfare were included. They organized into more than 120 committees and undertook, by research and collection of knowledge, a study of the problems involved. The results of the year's work were presented before the delegates assembled in Washington, November 19-22. More than 3,000, including physicians, psychologists, educators and administrators, were in attendance at the request of the President, as representatives of federal departments, states, cities, national organizations and the medical profession. The conference organized into four sections. Section 1 was on medical service, under the chairmanship of Dr. Samuel M. Hamill; section 2 on public health service and administration, under the chairmanship of Surg. Gen. Hugh S. Cumming; section 3 on education and training, under the chairmanship of F. D. Kelly, Ph.D., and section 4 on the handicapped, prevention, maintenance and protection, under the chairmanship of C. C. Carstens, Ph.D.

President Hoover, in his address at the opening session held in Constitution Hall, said that the problems of the conference fall into three groups: (1) the protection and stimulation of the normal child, (2) aid to the physically defective and handicapped child, and (3) the problems of the delinquent child. One of the committees reported, the President said, that among 45,000,000 children there are 35,000,000 who are reasonably normal, 6,000,000 improperly nourished, 1,000,000 with defective speech, 1,000,000 with weak or damaged hearts, 675,000 who present behavior problems, 450,000 who are mentally retarded, 382,000 tuberculous, 342,000 with impaired hearing, 300,000 who are crippled, 50,000 partially blind, 18,000 totally deaf, 1,400 wholly blind, 20,000 delinquent, and 500,000 who are dependent. "If we could have" the President continued "but one generation of properly born, trained, educated and healthy children, a thousand other problems of government would vanish. . . . These are a part of the problems that I charge you to answer. This task that you have come here to perform has never been done before. . . . From your explorations into the mental and normal endowment and opportunities of children will develop new methods to inspire their creative work and play, to substitute love and self-discipline for the rigors of rule, to guide their recreations into wholesome channels, to steer them past the reefs of temptation, to develop their characters, and to bring them to adult age in tune with life, strong in moral fiber, and prepared to play more happily their part in the productive tasks of human society."

The second general session was addressed by James J. Davis, Secretary of Labor, who said that "If we could put into practice what we know about safeguarding the health of children, preventing a deficiency and delinquency, and providing opportunities for wholesome group activities, we could in a single generation profoundly improve the whole character of our national life. The long, unhappy procession of children who enter adult life, physically, socially and mentally handicapped, could be made a much shorter one and the efficiency of our citizens be correspondingly increased."

The section meetings were held in Constitution Hall, the Corcoran Art Gallery, the National Academy of Sciences Building and the American Red Cross Building. The findings and conclusions of the year's intensive study of childhood, which may be used as a national standard for local legislation and for the guidance of welfare activities and scientific research, were adopted at the final meeting. The summary report of Section 1 on medical service follows:

A. THE COMMITTEE ON GROWTH AND DEVELOPMENT

1. Knowledge of the growth and development of children is extensive in some respects but meager in others. It is important to recognize the gaps which exist and to admit ignorance, rather than to theorize with unwarranted assurance.

2. Knowledge of the processes of growth and development during the first few weeks of life and the period of adolescence is particularly inadequate. In future studies, special consideration should be given to these two age periods.

3. A still more satisfactory understanding of the fundamental processes of mental and physical growth and development is clearly needed. This demands unremitting, conscientious and cooperative research by the laboratory worker, the clinician and all others cooperating in the study of the child.

4. The social and economic conditions of a child's surroundings may exert a profound influence on his development, both physical and mental. Nutriment, fatigue and such other factors as the competence of the parents, educational opportunities, the unusual hazard of disease, and so forth, are of the utmost importance and must be evaluated at all times. Scientific investigation of the factors from which clean-cut deductions may be drawn is difficult. Studies beginning with clear definitions of terms and definite objectives need to be undertaken.

5. Mental and emotional factors have an important bearing on physical health. This implies that the doctor, in particular, should endeavor to understand the causes of behavior of his patients, and, above all, he should assist parents to develop a sound point of view in regard to the general management of the life of their children.

6. Opportunity should be afforded every child for nutrition which to the best of our present knowledge is optimal for his needs. A well balanced diet must include both in quantity and in quality all the elements essential for the demands of the processes of growth. The provision of a liberal quantity of milk and of eggs, fruits and green vegetables provides a valuable safeguard.

7. Mothers should be encouraged to nurse their babies. Human milk from healthy and properly nourished mothers is the ideal food for infants. Artificial feeding in cases of necessity may be a satisfactory substitute when conducted with understanding medical supervision.

8. No single set of facts, such as height and weight, is adequate in itself to appraise and pass judgment on the health of the child. Mental and physical factors, his previous history, his race, his present condition, his opportunities and background, all are important. The normal differences which exist between individual children must be given due weight.

9. Periodic health examinations constitute a valuable safeguard to health. These examinations should begin with the new-born infant to be repeated at suitable intervals thereafter. These should not cease with entrance to school, but should be conducted at least through adolescence. Periodic examinations should be thorough and comprehensive, and be conducted by physicians acquainted with the healthy child and the complexities of growth and development, as well as the manifestations of the diseases peculiar to the different age levels. Reliance on superficial routines and unthoughtful application of so-called standards must be guarded against constantly.

10. Disease influences detrimentally the growth and development of children. The best treatment is prevention.

B. THE COMMITTEE ON PRENATAL AND MATERNAL CARE.

1. Infant and maternal mortality and disability are unnecessarily high. The main causes for the mother are infection, toxemia, hemorrhage and injury. For the infant they are prematurity, birth injury, malformations and infection.

2. These casualties can be reduced by adequate maternal care throughout pregnancy, labor and the lying-in period. The infant from the moment of birth requires adequate medical attention just as much as the mother.

3. The universal application of our present obstetric knowledge would markedly improve these conditions. The public needs further education as to the necessity of adequate facilities for maternal care and for the education of trained personnel. The various methods now in use for educating the pregnant woman and the public are all effective and should be continued. Interested national organizations perform a valuable function in initiating and advising local efforts. While local activities should conform to certain essential standards, too much standardization destroys local initiative.

4. Adequate care for maternity cases in the home and hospital with segregated maternity services should be available in every urban and rural community. A comprehensive program requires the cooperation of obstetrically trained doctors and nurses, and certain nonmedical workers in the fields of social service, domestic economy and nutrition.

5 There should be some modification of the methods of reporting and classifying stillbirths and early infant and

maternal deaths. It is particularly unfortunate that previable infants who have no possible chance of survival are now reported as live births. This leads to an unduly high figure for early infant mortality. More accurate statistical data as to the number and causes of deaths will lead to a better understanding of causes and a more effective prevention of such casualties.

6. Midwives are still needed in certain rural localities because of racial and economic conditions. As long as the necessity exists, more adequate provision should be made for their training and for proper supervision under medical control.

7. Nurses constitute an important agency in maternal care. Their undergraduate and graduate training in this field should be encouraged and improved. There is special need for better training of nursing instructors. The training of nursing attendants for maternity care should also be considered.

8. Adequate medical education is fundamental to any program for maternal care. We recommend the following specific improvements:

> A more thorough correlation of obstetric teaching with the basic sciences.
>
> Enlargement of women's clinics wholly under the control of medical schools.
>
> Residence of medical students in such women's clinics where they may for a sufficient length of time receive correlated practical teaching in maternal and infant care.
>
> Personal supervision by an obstetric teacher of all home deliveries by students.

Increased facilities in the medical schools will also provide postgraduate training for those who wish to become specialists, investigators and teachers, and for the general medical practitioner who wishes to improve his obstetrical knowledge.

Institutions for medical education and service require adequate financial support.

C. THE COMMITTEE ON MEDICAL CARE FOR CHILDREN.

The results of the various investigations have brought out certain facts and led to certain definite conclusions.

1. There is an enormous amount of preventive work being carried on by individuals and by groups of individuals which is incomplete and wasteful because uncoordinated. There are few communities where a complete child health program is being carried out. Careful studies of local situations should be carried out locally for or by the parties concerned in order to develop more complete coordination.

2. There is abundant evidence of lack of appreciation of the value of preventive measures by the laity. Intensive popular education is still greatly needed and should be undertaken. In such a campaign the assistance of the lay press is essential. The carrying out of preventive measures is part of the responsibility of the general practitioner and his cooperation should be sought.

3. There is little definite knowledge of the extent of bad body mechanics or "posture." Its effects on health, in the opinion of many physicians, are proved from experience with small groups of children. Extensive careful scientific investigation should be carried out in many localities and among all classes of the population to determine its extent and effect.

4. The practice of oral hygiene and reparative dentistry, carried on for a number of years, while improving general health, has failed to decrease the incidence of dental caries among children. Such work should be continued and extended, but intensive experimental and clinical work on a large scale should be undertaken to determine definitely the part played by mineral metabolism as influenced by dietary procedures in the incidence of dental caries.

5. Curriculums of educational institutions for physicians, dentists, nurses and physical therapists show great variations and in many cases utterly inadequate attention to preventive measures. Administrative authorities in the various schools should be urged to seriously consider the adequacy of their curriculums for preparing their students to give advice regarding essential preventive measures.

6. Conferences with various professional educational groups should be held to consider minimum essentials of education in preventive measures and the best practical way of adjusting curriculums to meet these needs.

7. While the committee has not investigated the extent to which measures for safeguarding the health of children in activities where health is not the primary purpose, it wishes to emphasize its conviction that in every activity for children such measures are of very great importance, are often neglected, and should always be provided under competent medical supervision.

REPORT OF SECTION ON PUBLIC HEALTH SERVICE

The summary report of section 2 on public health service and administration follows:

The three committees of section 2 presented to the conference detailed reports and discussions of their work and their findings. With one exception the reports were favorably received by the delegates who came to hear them.

The outstanding facts which were developed by the Committee on Communicable Disease Control, of which Dr. George H. Bigelow is the chairman, are that: 1. The knowledge of control in many communicable diseases exceeds its practical application. Existing knowledge, if generally applied, would result in a marked reduction in the prevalence of these diseases. 2. There are, however, many gaps in our knowledge concerning the results of present measures, and the fundamental facts of cause, distribution, prevention and control of many of the communicable diseases. This knowledge, when supplied, will greatly simplify and focus efforts toward control. 3. Consequently, differences in opinion and practice exist concerning the procedures to be followed to prevent or diminish the prevalence of communicable disease. Such differences will be resolved only when more precise knowledge is available. The committee emphasized the necessity for well equipped full time public health service with competent personnel for urban and rural districts, with adequate community support and legal powers relative to all phases of preventive medicine.

The Committee on Milk Production and Control, of which Mr. H. A. Whittaker is the chairman, emphasized the fact that the consumption of fluid milk in the United States is too low for proper and economical human nutrition. This country is far below the optimum daily consumption of milk for the normal child. Health agencies both official and voluntary should more actively encourage greater use of high quality milk as a nutritional and health protective program. The best information available indicates that approximately one quart of milk is desirable daily for the average growing child; but the average child receives considerably less than this amount.

While marked improvement in the sanitary quality of milk has been brought about during the past several years by agricultural and public health agencies, the investigations of the committee indicate that there is need for further improvement in the public health and quality supervision of the milk supply of this country. The committee specifically recommended that uniform requirements should be incorporated in laws or regulations for the supervision of milk supplies at least the equivalent of those contained in a milk ordinance to be recommended by the United States Public Health Service and the Bureau of Dairy Industry of the United States Department of Agriculture. It is fundamental that all milk supplies should be surveyed and rated as frequently as practicable.

The committee is of the opinion that the general market milk should be pasteurized before it is consumed. Attention was called to the outstanding achievement of the federal Department of Agriculture, attained through its interest in the development of accredited herds throughout the country. Systematic work along this line began only ten years ago but far reaching results have already been obtained.

The Committee on Public Health Organization, of which Dr. E. L. Bishop is the chairman, states in its report that public health administration is a relatively new science, because only in fairly recent years has there been sufficient knowledge in regard to the etiology of disease to make possible the application of specific control measures. It is a difficult science because it involves in addition to other complexities the problem of human relationships. Methods relative to the application of knowledge have therefore lagged behind the knowledge of laboratory science on which administrative practice is based. These facts have made the task of the committee especially difficult because there were no blazed trails for it to follow. It has, however, endeavored to prepare, from a completely detached point of view, an outline of procedure which in the opinion of its members would best integrate public health procedure into the administrative scheme of the three elements of American government.

The report of the Subcommittee on Federal Health Organization, of which Dr. Haven Emerson is the chairman, contained one phase which met with vigorous protest by many of the members of the conference to whom it was presented on the second and third days of the meeting. The point at issue involved the conclusion that authorization should be provided for the transfer of the functions, together with the personnel and necessary appropriations for their support, of the health activities of the Divisions of Child Hygiene and of Maternity and Infancy of the Children's Bureau to the Public Health Service, except so far as they are concerned with health studies inseparable from and indispensable to the functions of this bureau in the field of welfare of women and children. It was suggested, therefore, that in conformity with the wishes expressed by the President this point of controversy be referred to a continuing committee of the conference for further consideration, and that the report of the subcommittee as originally presented, together with the subsequently submitted dissenting opinion of Miss Abbott, be included in the final publication of the conference, with a note indicating that this matter is subject to further consideration by a continuing committee as proposed by the President.

A major recommendation of the Subcommittee on Federal Health Organization was the continuance and increase of federal agents in aid with the object of developing competent health organization in rural communities throughout the country serving the general as well as the special health needs of children.

The Subcommittee on Federal Health Organization, of which Dr. John A. Ferrell is the chairman, advocated for state health departments the establishment of an organization composed of full time trained personnel to carry on the necessary administrative and special functional public health activities. It is believed that the state should join with the counties or other local governments administratively and financially in organizing and conducting adequate local health service. It is of further opinion that the federal government, through the state health departments, should supply to the various states in proportion to their needs, the personnel and money necessary to guarantee to every community in the nation a health service that will be able to maintain at least what the authorities may designate as a recognized standard of adequacy.

The Subcommittee on City Health Organization, of which Dr. Henry T. Vaughan is the chairman, emphasized the well recognized fact that no municipal health organization has divided its functions according to the race or age distribution of its population but has so coordinated each of its special functional divisions that they contribute most effectively directly to the improvement of child health and protection. A true test or measure of the successful operation of a city health department consists in the lowering of infant mortality and the improvement of the health level of the child and of the community.

The Subcommittee on Rural Health Organization, of which Dr. Allen W. Freeman is the chairman, calls attention to the fact that, whereas the cities are provided with various institutions in the interests of the health and welfare of the child, the rural areas must rely almost entirely on the county health unit for the problems involved in child health and in the protection of the community in health affairs. The sole and indispensable agency of health throughout the country for rural communities is the local full time health organization as now promoted and to a degree supported by federal grants in aid through state departments of health to individual counties. The committee advances the opinion that federal aid in promoting and maintaining county health departments has proved its utility and should be largely extended.

The Subcommittee on the Relation of Official and Nonofficial Agencies in Public Health Organization urged the necessity for paralleling official health organization locally and nationally by rural health councils which will permit the coordination of official and voluntary health agencies in rural communities, and the true coordination of national health agencies among themselves in order to avoid conflicting and competing appeals to the public for the health interest of the child.

The Subcommittee on Training of Health Personnel, of which Dr. W. S. Leathers is the chairman, emphasized the great need for educational institutions and government medical services utilizing the facilities for training health personnel. One of the most significant trends in providing trained health personnel is to develop, in medical schools, well organized and properly financed departments of hygiene and preventive medicine so that physicians may have a knowledge and an understanding concerning the part which they should play in the prevention of disease as practitioners of medicine. From this group will be obtained health officers, and, in order to stimulate interest on the part of medical students to adopt public health as a career, it is fundamental that they be stimulated as undergraduate students in going into this field of medical service.

The training of health personnel also involves providing proper facilities for the training of nurses and sanitary inspectors. A report of the subcommittee developed the great need of providing better facilities for training nurses in schools of nursing in conjunction with departments of hygiene and preventive medicine in medical schools. It is realized that efficient public health work can be done only by having properly trained personnel, and the whole advance in public health organization depends on those who are effectively trained.

Important features of the report of the Subcommittee on the Administration of Child Health Work as a part of the Official Health Program, of which Dr. Anna E. Rude is the chairman, are as follows: All child health activities, whether federal, state or local, as well as activities sponsored by private agencies, should be coordinated and supervision or direction given by the constituted official health agencies; that these child health activities should be standardized so as to be scientifically sound; that extension of child health activities with emphasis on preventive health measures directed to the early age group is indicated, and, finally, that increased federal, state and local, as well as private appropriations are necessary to perfect and extend further child hygiene activities.

The Subcommittee on Practitioners of Medicine and Dentistry in Relation to Health Programs, of which Dr. David Chester Brown is the chairman, calls attention to the fact that there are certain phases of public health work which are especially well adapted for developing a constructive program of cooperation between health agencies and the physicians and dentists of a community. The state and local health departments should advise with the medical and dental professions in determining such programs. The state medical and dental associations should appoint, for the benefit of the state health officer, advisory committees approved by their legislative bodies. Likewise, the district or county organizations should appoint advisory committees for local health officers. These committees will prove invaluable in adjusting differences, stimulating interest and securing cooperation on the part of practitioners. Practicing physicians and dentists are, and should be, very important factors in safeguarding the health of the public. Therefore, any method employed in public health administration which tends to destroy the confidence of the community in these professions is not in the interest of human welfare and should not be tolerated.

REPORT OF SECTION ON EDUCATION AND TRAINING

Section 3, on education and training, pointed out in its report that the statements commonly heard about the youth of today running wild were not substantiated by the studies made for this conference. The present agencies for child education and training in general are alert and managed by competent men and women. What is needed is continuous critical and sympathetic study of these agencies, and then encouragement and support of the programs evolved. Society must demand for every child his right to a fair chance and that involves first that he shall be born right, that he shall have a fair start and not be handicapped for life by a feeble endowment of body or mind. The welfare of a child depends on nothing else so inevitably as on the personality relationships within the family and the child's reaction to them. The best educational efforts of schools and other agencies may be ineffectual if the emotional background of the child's life is unhappy and insecure. A school health service, the report adds, is an essential part of every school organization. Parents, teachers, school authorities and health specialists should join in devising a program such as will assure the full safeguards of immunization, the early detection and exclusion of contagious diseases, and the discovery and correction of remediable defects of body and mind in all the children regardless of their economic status but above all the health program should systematically promote such a regimen of life—diet, sleep, work and play—as will contribute most to the full mental and physical vigor of every child.

REPORT OF THE SECTION ON THE HANDICAPPED

Section 4, on the handicapped reported that the proportion of children abused or wilfully neglected is small, but the aggregate mounts into the thousands and every locality has the problem in its midst. The more common of these abuses and neglects include failure to provide sufficient food and clothing and proper living conditions and needed medical and surgical treatment, as well as the exposing of children to immoral associations. About 1,500 foster institutions and 350 foster family agencies cared for approximately 250,000 children during the last year, one third of whom were in foster families. On the basis of the best available statistics, the report says that about 200,000 different delinquent children in 1928 were dealt with by various courts of the country and that this is only a fraction of all delinquents, as a great many are handled by the police and other agencies without resort to the courts. The report suggests that out of this conference may grow a committee, under the Department of Labor, representing the professions and leaders in industry, education and social work to undertake a practical solution of the difficulties that confront handicapped children. The report also recommended that the work of the national organizations dealing with special types of handicaps coordinate their work into a National Council on the Handicapped, which might have some federal bureau act as a research bureau and clearing house of information for the various states. The report of section 4 was, in part, as follows:

> If there are from three million to five million children in the United States, as it is believed, who are handicapped in the ordinary sense of the word, namely, children who are blind and partly seeing, who are deaf and hard of hearing, who are crippled, who are mentally defective or who are suffering from tuberculosis, heart disease or parasitic diseases, the problem of the care of these children becomes a major obligation of this nation and of its constituent states. Much has been done already through public and private service, but there are wide areas, especially the rural sections of our various states, that are a veritable No Man's Land—areas where handicapped children in desperate need grow up and die without ever hearing of efforts in their behalf. The various groups have special needs but there is at least one fundamental principle that may be expressed as lying back of all the work that needs to be done and that may read as follows:
>
> Like every child, the child who may have some physical or mental handicap is to be regarded as a potential social asset and not a liability. The handicapped child should be so guided that his aptitudes and abilities may be given the fullest development and that his life may become one of usefulness, success and happiness.
>
> Children who are physically or mentally handicapped are not *peculiarly set apart from other children. Their likenesses to* other children are greater than their differences. They require, however, more intensive application of medical care and of academic and social care and treatment to equip them to participate as fully as possible in the normal life of the community.
>
> For the handicapped child in need of temporary institutionalization, the institution should provide treatment, care and training looking toward the child's rehabilitation and restoration to community life. For the handicapped child in need of more permanent institutionalization, institutions should provide adequate treatment, well rounded custodial care and training which utilizes the child's mental or physical abilities to the best advantage during his institutional life.
>
> In the study of the six groups of the physically and mentally handicapped, certain additional general needs have come increasingly to the front; namely, early diagnosis, specialized treatment and individual health education, the largest possible cultural education that the child is able to enjoy and absorb, specialized vocational guidance, vocational education and advantageous placement with careful follow-up. The special training and education required on the part of these groups is more expensive than the education of the ordinary child, but the additional cost is inconsiderable when compared with the expense that the child who is untrained and unequipped for the world's work lays upon the community during the rest of his life.
>
> In order that the needs of these handicapped children may have careful consideration and may be fully met, it is necessary that there shall be a central state coordinating agency closely linked up with the Department of Public Welfare or one of its divisions.
>
> One of the major possibilities of the White House Conference on Child Health and Protection in respect to the handicapped would be achieved if there could be sponsored under the Department of Labor a committee representing, on the one hand, leaders in industry, commerce and the professions, and, on the other hand, the medical, educational and social work groups who are daily dealing with the problems of physically and mentally handicapped with the idea in mind that through such a committee a practical solution of the difficulties that confront the handicapped could be worked out.
>
> The committee dealing with the physically and mentally handicapped joins with the Committee on Special Classes of the Section on Education and Training in recommending that national organizations dealing with special types of handicaps coordinate their work in a National Council on the Handicapped. The recommendations of the White House Conference on Child Health and Protection to promote public information about the handicapped and the means of amelioration, treatment, cure, training and placement should be given careful consideration by this council so that contacts may be made with the appropriate administrative agencies in the counties and other political units in the states and that the findings, conclusions and recommendations of the White House Conference may be made increasingly effective in the several states. Such a council could do its best work if as a result of this conference some appropriate federal government bureau could be designated as the proper agency to act as a research bureau and clearing house of information for the various states and if in each state a state advisory council for handicapped children could be created, made up of representatives of state organizations interested in such children, to cooperate with the national council and to aggressively promote in the states measures for making effective the recommendations of the White House Conference.
>
> The United States is conducting forty-eight or more different experiments in the field of child care in its various states and territories. These experiments are based on certain fundamental principles that lie back of all of them but are modified by the variety of races and nationalities served and by the various Old and New World traditions found in their populations. It is clear that there is no one panacea in organization for child care, but the experience of one state has definitely modified the forms in other states and so the diversity we often decry has once more proved of value.
>
> The services are very diverse. While there are localities and even states that are inclined to "enjoy" unmolested whatever standard of public administration is desired by its people, this attitude is rare. In spite of this diversity, there is an approximation even now to a "national minimum," but its terms need to be understood and more definitely interpreted in order that it may adequately express our standards of health, happiness and general welfare for all children throughout the country. The development of standards is an evolving process as new needs and new possibilities appear and must be carried on by each state independently and by the federal government in cooperation with the various states.

SUMMARY OF THE CONFERENCE BY DR. WILBUR

The work of the White House Conference on Child Health and Protection was summarized, Saturday evening, November 22, in a nation-wide radio talk by the chairman of the conference, Dr. Ray Lyman Wilbur. Among other things, Dr. Wilbur said:

"Every child is entitled to be understood, and all dealing with him should be based on the fullest understanding of the child.

"Every prospective mother should have suitable information, medical supervision during the prenatal period, and competent care at confinement. Every mother should have postnatal medical supervision for herself and child.

"Every child should receive periodical health examinations before and during the school period, including adolescence, by the family physician or the school or other public physician, or such examination by specialists and such hospital care as its special needs may require.

"Every child should have regular dental examination and care.

"Every child should have instruction in the schools in health and in safety from accidents, and every teacher should be trained in health programs.

"Every child should be protected from communicable diseases to which he might be exposed at home, in school or at play, and protected from impure milk and food.

"Every child should have proper sleeping rooms, diet, hours of sleep and play, and parents should receive expert information as to the needs of children of various ages as to these questions.

"Every child should attend a school which has proper seating, lighting, ventilation and sanitation. For younger children, kindergartens and nursery schools should be provided to supplement home care.

"The school should be so organized as to discover and develop the special abilities of each child, and should assist in vocational guidance; for children, like men, succeed by the use of their strongest qualities and special interests.

"Every child should have some form of religious, moral and character training.

"Every child has a right to play, with adequate facilities therefor.

"With the expanding domain of the community's responsibilities for children, there should be proper provision for and supervision of recreation and entertainment.

"Every child should be protected against labor that stunts growth, either physical or mental; that limits education, that deprives children of the right of comradeship, of joy and play.

"Every child who is blind, deaf, crippled or otherwise physically handicapped should be given expert study and corrective treatment, where there is the possibility of relief, and appropriate development or training. Children with subnormal or abnormal mental conditions should receive adequate study, protection, training and care."

Book Notices

The Principles and Practice of Medicine: Designed for the Use of Practitioners and Students of Medicine. Originally written by the late Sir William Osler, Bt., M.D., F.R.S. Eleventh edition revised by Thomas McCrae, M.D., Physician to the Jefferson and Pennsylvania Hospitals, Philadelphia. Cloth. Price, $7.50. Pp. 1237. New York: D. Appleton & Company, 1930.

Not many medical books are as easily recognized on library shelves as Osler's Practice of Medicine. It has been used as a textbook in medical schools for many years. The eleventh edition retains binding, color and size similar to that of its predecessors. Indeed, the aim of the editors since the death of Osler has been to retain in each edition the reading material also that is characteristic of him. Many new subjects, however, have been added, a few of which are poisoning from radioactive substances, poisoning from methyl chloride, hypoglycemia, asbestosis, pentosuria, lipoid histocytosis and infantile splenic anemia. This volume, as some of the others, is dedicated to three teachers of William Osler, namely, William Arthur Johnson, James Bovell and Robert Palmer Howard, with whom one becomes so well acquainted in Cushing's biography.

Les groupes sanguins, schémas et applications pratiques: La transfusion sanguine, technique et indications. Par Paul Michon, médecin des hôpitaux de Nancy. Paper. Price, 16 francs. Pp. 120, with 7 illustrations. Paris: Masson & Cie, 1930.

The aim of this little book is to describe clearly (1) the curious phenomenon of iso-agglutination of human blood and the technic of determining the blood groups and (2) the method and indications of blood transfusion. The medicolegal applications of blood grouping are considered also. The booklet is recommended as a reliable guide in its field. Attached to the booklet are no less than forty-eight pages of advertising matter relating to books issued by the publishers.

Fundamentals of Dietetics: A Text-Book for Nurses and Dietitians. By Bertha M. Wood and Annie L. Weeks. Second edition. Cloth. Price, $1.75. Pp. 243. Philadelphia: W. B. Saunders Company, 1930.

This is a textbook on dietetics for the teacher of nurses and for the nurse herself during her student training and for her guidance after graduation. The more recent ideas of nutrition are incorporated. The subject is presented in two courses: course I, preliminary dietetics, comprising fourteen lessons each consisting of a lecture and associated laboratory, experimental or demonstration work, and course II, advanced dietetics, comprising ten lessons each consisting of a lecture and appropriate laboratory or demonstration work. The book is intended to promote the importance of dietetics in the curriculums of nursing schools. The practice of medicine is giving more and more consideration to dietotherapy in the prevention and cure of disease. The practice of nursing requires a similar appreciation of the value of dietotherapy and an appropriate training to apply its principles efficiently in cooperation with the medical man. The fundamentals of dietetics are presented in language befitting the academic training of nurses and in an easy flowing manner that maintains interest. The lectures are well balanced with practical demonstration work. All essential topics of dietetics are covered in sufficient detail to enable the nurse to undertake her duties in practice intelligently. The simple classification of topics is convenient for quick reference. The general information on specific diets for disease conditions is helpful and practical. The book along its present lines is sufficiently meritorious to deserve frequent revisions to keep it abreast of dietetic developments.

Trauma, Disease, Compensation: A Handbook of Their Medico-Legal Relations. By A. J. Fraser, M.D., Chief Medical Officer, Workmen's Compensation Board, Winnipeg. Cloth. Price, $6.50 net. Pp. 524. Philadelphia: F. A. Davis Company, 1930.

The author has compiled the opinions of physicians, surgeons, industrial boards and courts concerning the relations of many diseases and injuries to trauma of all kinds and to other occupational hazards. These opinions range over the entire medical field, from status lymphaticus, angioneurotic edema and auricular fibrillation to hernia, fractures, caisson disease and injuries to the spinal cord. The book thus affords ready access to many important opinions. Its usefulness is greatly diminished, however, by the looseness of its citations to original sources. Most readers, in order to learn the facts, hypotheses and theories on which the opinions are based, will find it necessary to read them in the words of those who expressed them. Without such appraisal, the weight to be given an opinion cannot be determined by courts and industrial boards, and the opinion is of no value to the expert witness in formulating his own opinions and supporting them in the face of cross-examination. Statements of the exact sources of the opinions abstracted, giving the year of publication and citing volume and page numbers, would have relieved from much labor those who use the book and would have added greatly to its usefulness.

Vom Lokalisationsproblem der artikulierten Sprache. Von Erwin v. Niessl-Mayendorf. Aus dem Institut für Hirnforschung der Universität Leipzig, Direktor Prof. Dr. Schröder. Paper. Price, 24 marks. Pp. 186, with 70 illustrations. Leipzig: Johann Ambrosius Barth, 1930.

After studying a case of motor aphasia with such multilocular and extensive destructions of the brain that it hardly appears suitable for any valid conclusions, the author feels entitled to assert that the aphasic symptoms were due to the interruption of the association fibers (arcuate bundle) connecting the left auditory center (almost completely destroyed, left internal geniculate body atrophic!) with the lower segment of the left precentral convolution. The motor aphasia was not due to the destruction of the left operculum of Broca, which was found on both sides intact. There does not exist, according to von Niessl-Mayendorf, a special motor center for speech in the Broca region; the cortical speech mechanism is composed merely of two stations: of a sensory region close to the auditory projection center (and perhaps including the latter), and of the lower portion of the precentral convolution, which is identical with the region wherefrom efferent pyramidal fibers of the tongue, lips and face arise. Thus the same cortical motor centers are involved in the motor speech that are otherwise active in movements of the corresponding groups of muscles. A separate superimposed motor center that would be concerned with the motor speech alone and would direct the action of the precentral motor foci does not exist. Accordingly, there does not exist an anatomically preformed motor speech mechanism. The true speech center is the temporoparietal region. (This is the maximum that von Niessl-Mayendorf concedes to the localistic point of view, since "the anatomically preformed center of speech must be denied, though a localizable physiological speech mechanism must be accepted"!) There the speech is localized, although "only in a diffuse way." The impulses arising in this speech center arrive by way of the association fibers directly to the precentral motor foci. If these association connections are interrupted, the result is the impairment of the motor speech with the receptive function in speech preserved.

In general, von Niessl-Mayendorf rejects the concept of the localization of speech as of most other functions in narrow cortical localities. Speech is, according to him, a product of a finely adjusted integration of the activity of many parts of the cortex, especially of the sensory regions. This is in accord with his views on the organization and function of the cerebral cortex in general. Though these views appear in many points contradictory and inconsistent, the salient point is the rejection of Flechsig's division of the cortex into projection and association regions. The so-called projection regions participate also in "higher" processes. Already the most primitive sensory function is not merely a physiologic but a psychic process as well. The same regions of cortex when stimulated from the receptor organs produce subjective "impressions," give rise to "memory images" when stimulated from within. There do not exist, therefore, separate association as mnemonic regions, distinct from the projection areas. The cerebral function nowhere can be localized and uses as its instrument of expression both hemispheres, which work as a whole. In such a way von Niessl-Mayendorf identifies himself with the rest of modern decentralists (Pierre Marie, Monakow et al.). The morphologic investigation of the cerebral cortex, according to him, has no validity. There does not exist a parallelism between the form-structure and the function. The morphologic differentiation of the cortex has no importance, there exists only a physiologic difference in cortical loci. The human speech can never be based on the presence of certain cells or a special cortical architecture, but exclusively on a purely functional combination of certain cell groups, which never are embodied into the anatomic structure. The author will have a hard task to convert modern neurologists to his conceptions, least of all by using these arguments and by rejecting others which must be accepted as facts by every unbiased scientist.

Introduction to Physiological Chemistry. By Meyer Bodansky, Ph.D., Director of Laboratories, John Sealy Hospital, Galveston. Second edition. Cloth. Price, $4 net. Pp. 542, with 46 illustrations. New York: John Wiley & Sons, Inc., 1930.

This, like the first edition, is an excellent textbook for medical students. The general plan of the original edition is adhered to with the addition of a chapter on the source and composition of foodstuffs and another on the composition of milk and certain tissues. Much of the material has been rewritten and extended so as to include the more recent advances, thus resulting in the addition of approximately 100 pages. The work is well indexed and the more important recent observations referred to in the text are made much more valuable by references to the original articles. The author is to be congratulated on his success in presenting so much and so many types of material in a well organized manner without sacrificing style and accuracy too much.

A System of Clinical Medicine Dealing with the Diagnosis, Prognosis, and Treatment of Disease for Students and Practitioners. By Thomas Dixon Savill, M.D. Eighth edition. Leatherette. Price, $10 net. Pp. 1019, with 167 illustrations. New York: William Wood & Company, 1930.

The author endeavors to cover the field of medicine in one volume which, while growing somewhat from edition to edition, still remains a handy size. It has been necessary, however, to use much small type. The first chapter remains just as the author wrote it for the first edition. The first part of each chapter deals with symptoms and their causes. Another feature is italicized paragraphs in part C at the head of each chapter which deal with a separate malady and emphasize the features for which one disease may be differentiated from another in the same group. Every part of this edition has been revised, many of the chapters have been recast, and new matter has been added on such subjects as tularemia, undulant fever, insulin coma, liver therapy, quinidine treatment and coronary thrombosis. There are many pictures, a few in color.

Recent Advances in Chemotherapy. By G. M. Findlay, O.B.E., M.D., D.Sc., Wellcome Bureau of Scientific Research, London. With a foreword by C. M. Wenyon, C.M.G., C.B.E., M.B., Director-in-Chief of the Wellcome Bureau of Scientific Research, London. Cloth. Price, $3.50. Pp. 532, with illustrations. Philadelphia: P. Blakiston's Son & Company, Inc., 1930.

This is an interesting history of chemotherapeutic agents and their effects on certain diseases. Each chapter is a digest of the results obtained on one disease, and each is followed by references to the original literature, making the volume bibliographically valuable. Much of the text is concerned with diseases due to protozoa, spirochetes and helminths, because most of the chemotherapeutic work has been along this line. Many of the diseases mentioned are much commoner in other countries than in the United States. The book is really a review of the literature and not a critical evaluation of the status of the various drugs. Conspicuous by its absence is the lack of excellent opinions by some American authors, including the many reports of the Council on Pharmacy and Chemistry. This may be due to the fact that the book emanates from the Burroughs Wellcome employees and naturally would be flavored with the English attitude. The field is one that is in need of good reference books. To some extent Findlay's contribution will fulfil the need and should be in the library of those interested in chemotherapy. It is not, however, as authoritative a treatment as is the book of Kolmer in the limited field of chemotherapy of syphilis.

The Principles of Bacteriology and Immunity. By W. W. C. Topley, M.A., M.D., M.Sc., Professor of Bacteriology and Immunology, University of London, and G. S. Wilson, M.D., M.R.C.P., D.P.H., Reader in Bacteriology and Immunology in the University of London. In two volumes. Cloth. Price, $15 net. Pp. 1300, with 242 illustrations. New York: William Wood & Company, 1929.

In the medical curriculum, the demands on the student's time are so great as to permit only the merest acquaintance with the fundamentals of bacteriology, various conceptions of immunity and the relationship of this knowledge to the diagnosis and treatment of diseases. Bacteriology is a profession in itself, and its applications extend to every phase of human existence. Knowledge grows constantly, and there is need for a complete systematic reference to facts and current conceptions in this field. The book is divided into four parts including general bacteriology, systematic bacteriology, infection and resistance and the application of bacteriology to medicine and hygiene. Thus, while volume I will be for the physician merely a reference work, volume II is for any medical reader a means of bringing himself up to date and acquainting himself with all that is known and established concerning the control of infectious diseases. The book is thorough, with complete references to medical literature. The history, causes, methods of infection, serology, diagnosis, prevention and treatment of infectious disorders is fully elucidated. Each chapter is followed by a carefully prepared bibliography, and a good index makes reference to any special subject simple.

A Text-Book of Materia Medica for Nurses Including Therapeutics and Toxicology. By George P. Paul, M.D., C.P.H. Sixth edition. Cloth. Price, $1.75 net. Pp. 356. Philadelphia: W. B. Saunders Company, 1930.

The value of this volume would seem to be chiefly as a work of reference, for one certainly could not expect a nurse to memorize, much less to comprehend, the barrage of facts it directs against her. It is a good deal like a compend intended for medical students. Special commendation must be given the care with which are detailed the "pretoxic signs" or warnings of the beginning of toxic effects. The use of the old system of weights and measures throughout the book is one of the evidences of the conservative, not to say reactionary, tendency of the author.

Report on a Study of the Nasopharyngeal Bacterial Flora of a Group of the Manchester Population During the Period July, 1925, to September, 1927. Ministry of Health. Reports on Public Health and Medical Subjects, No. 58. Paper. Price, 6d. net. Pp. 29. London: His Majesty's Stationery Office, 1930.

This pamphlet is a report on a bacteriologic study of greatest interest and the size of the publication is no criterion of the immense amount of intelligent, painstaking labor that must have been put into the investigation. Proceeding under the assumption that there might possibly be a change in the bacterial flora of the throat and air passages of normal persons before an epidemic of acute respiratory disease, and that, from knowledge gained, means for prevention might be taken, a systematic survey of a large enough number of individuals over what was considered a fair period of time was undertaken. It was recognized how difficult such a study of influenza would be, when the causative organisms among other important factors are not well understood. The workers appreciated, too, as they stated, that while considerable information is present regarding the normal flora of the upper air passages, fluctuations due to persons and in relation to influenza and other infections have not yet been thoroughly studied. The organisms studied were pneumococci, influenza bacilli, gram-negative cocci and hemolytic streptococci. Interesting charts are given and attempts made to correlate the laboratory observations with the actual incidence and mortality from respiratory diseases over the period covered. There occurred a succession of epidemiologic events that were associated with a series of changes in the bacteriologic flora of a fairly large group of normal individuals. The report is highly recommended for study to all physicians interested in infections of the upper respiratory tract, their bacteriology and their seasonal and epidemiologic variations.

The Candirú: The Only Vertebrate Parasite of Man. By Eugene Willis Gudger, Ph.D., Bibliographer and Associate in Ichthyology, American Museum of Natural History, New York City. With a foreword by Aldred Scott Warthin, Ph.D., M.D., LL.D., Professor of Pathology and Director of the Pathological Laboratories in the University of Michigan, Ann Arbor. Cloth. Price, $1.50. Pp. 120, with 18 illustrations. New York: Paul B. Hoeber, Inc., 1930.

This is a corrected and enlarged reprint of an article in the *American Journal of Surgery,* June, 1930. Candirú is the collective name given to certain small catfishes of the Amazon River and its tributaries to which is assigned "the evil habit of entering the urethra of men and the vulva of women bathers, particularly if they micturate while in the water." The author has published interesting articles on live fishes impacted in the food and air passages of man, on poisonous fishes and fish poisons, and on stitching wounds with the mandibles of ants and beetles. In "The Candirú" he deals with another picturesque and out-of-the-way topic. A mass of testimony is set forth bearing on the curious habits of the little catfish of the Amazon basin, and the evidence does indicate that the fish may penetrate the urethra or vagina with painful and disastrous results. The story is well written, but evidence is not presented to warrant designating the candirú as "the only vertebrate parasite of man." Occasional entrance into a natural passage of the body does not constitute parasitism.

Hypertension. By Leslie T. Gager, M.D., Clinical Professor of Medicine in the George Washington University. Cloth. Price, $3. Pp. 158. Baltimore: Williams & Wilkins Company, 1930.

The gradually growing list of American monographs on medical subjects is enhanced by this fine contribution. The author has studied under leaders in the field of investigation concerned, and has extended his studies to the most recently available literature, which is covered in a bibliography containing some five hundred references included in the book. The monograph covers the subject of hypertension completely from the definition through the symptomatology, incidence, prognosis and treatment. It is sound in that it avoids strange notions and unestablished conceptions. By its aid the general practitioner will be enabled to come quickly abreast of modern methods of diagnosis and treatment and will receive a correct evaluation of new diets and new drugs used in the control of this condition.

A Text-Book of Psychiatry for Students and Practitioners. By D. K. Henderson, M.D., F.R.F.P.S., Physician-Superintendent, the Glasgow Royal Mental Hospital, and R. D. Gillespie, M.D., M.R.C.P., D.P.M., Physician for Psychological Medicine, Guy's Hospital, London. Second edition. Cloth. Price, $5.50. Pp. 526. New York: Oxford University Press, 1930.

The first edition of the book, published in May, 1927, has had a considerable success, and the authors have taken advantage of suggestions made by friends, and of additions to our knowledge of psychiatry, to make minor changes in the second edition. It is an objective presentation of psychiatric conditions. The case reports are detailed, the classification is modern, and the book, therefore, is one of the most suitable available for both the student and the practitioner. In the discussion of the treatment of epilepsy, too little is said concerning advantageous methods. The ketogenic diet is barely mentioned, and a great deal of space is given to diagnosis. The section on relation of psychiatry and the law is limited almost wholly to conditions in England and Scotland and will mean little to the American reader.

The New Evolution: Zoogenesis By Austin H Clark, U S. National Museum. Cloth. Price, $3. Pp 297, with illustrations Baltimore: Williams & Wilkins Company, 1930.

Since much of the furor in the argument between the fundamentalists and the evolutionists has died down, current interest in volumes concerning the subject may be said to be limited to students. Mr. Clark conceives the evolution of mankind as a part of a systematic process of evolution which he entitles "zoogenesis." He cites evidence to indicate that intelligence and reason are simply mental attributes that we think we understand, while instinct is a mental attribute we know we do not understand. Mr. Clark does not accept any theory of the origin of man from the anthropoid apes. Whereas evolution presupposes a gradually progressive process leading toward higher forms, zoogenesis indicates an independent development of all sorts of forms modified by numerous unusual conditions. The author believes that life at its very earliest developd at once and simultaneously from the single cell in every possible direction. Certainly, the evidence he submits to support his contention is sufficient to arouse belief in its reason.

Applied Physiology. By Samson Wright, M.D., M.R.C.P., Lecturer in Physiology, University of London, King's College. With introduction by Swale Vincent, M.D., LL.D., D.Sc., Professor of Physiology, University of London. Third edition. Cloth. Price, $5.50. Pp. 552, with 128 illustrations. New York: Oxford University Press, 1929.

More and more, medicine is getting back to a recognition of normals in both structure and function; hence, the popularity of a book like this one on applied physiology. The third edition takes into account many new observations, such as new tests for pregnancy, the utilization of fat and the conditional reflexes. The book has been carefully revised and new illustrations have been added. It is one of the most scientific and practical books available for the reader who wishes to keep abreast of the newer knowledge of physiology.

The Treatment of Schizophrenia. By Leland E. Hinsie, M.D., Professor of Clinical Psychiatry, College of Physicians and Surgeons, Columbia University. Cloth. Price, $3. Pp. 206. Baltimore: Williams & Wilkins Company, 1930.

This small volume contains a modern description of schizophrenia and summarizes the present-day trend of psychiatrists and psychoanalysts as well as medical men in general with regard to the treatment of schizophrenia. It is a well written and easily understandable monograph.

Children Are Like That. By C. Madeleine Dixon. Boards. Price, $2.50. Pp. 206, with illustrations. New York: John Day Company, 1930.

The author of this book has had experience in the management of nursery schools and in physical education in various groups. She is committed to teaching by play methods, leaving the child to develop its own urges, the parents and the teachers intervening when there is necessity for teaching good habits, danger of excesses or unbalanced choosing. She emphasizes especially the need for rest and serenity, for pleasure and the satisfaction of curiosity. The book is written in a playful tone, as though written for children rather than for adults. It is full of close observations of child life. The author recites commonplaces and puts them in italics, as though they were the observations of a new Plato or Socrates. Because of this method of presentation, the book is, for an adult, exceedingly tiresome. The illustrations are charming and the presentation of the book in the best style of the John Day press.

Doctor, Tell Me! By Charles M. Jacobs, M.D. Paper. Price, $2.50. Pp. 96, Springfield, Massachusetts: Victa Publishing Company, 1930.

This pamphlet is devoted to a few brief notes of information concerning the human body and its functions in health and disease. The price is exorbitant, since far more may be had for the same money from many other sources. In general the advice is sound.

The First Year of Life By Charlotte Bühler. Translated by Pearl Greenberg and Rowena Ripin. Cloth. Price, $3.50. Pp. 281, with illustrations. New York: John Day Company, 1930.

While this book is a refreshing escape from the usual literary effusion on the charms of babyhood, it does not fulfil the purpose assigned to it by the publishers. It is the first English translation of Charlotte Bühler's work on child psychology. As such it is a valuable contribution to American workers in this field. The author presents a scientific formulation of mental manifestations of growth during the first year of life on the basis of careful and painstaking observations. The text is divided into two parts by the translators. In the first part methods of observation, discussion of these observations and a quantitative analysis of the data are given. The second part deals with tests designed for the baby during the first two years of life and a discussion of these tests. The methods of study employed appear to be an extension of those of Arnold Gesell and his workers, with an attempt to formulate a standard of the average normal development for the first year of life. For those scientifically interested in child psychology, the data will be most interesting. However, it is doubtful whether the observations, valuable as they are, can be of much practical value for modern parents and nurses.

Medicolegal

Revocation of License for "Conviction" for Crime

(Donnell v. Board of Registration of Medicine (Me.), 149 Atl. 153)

The Medical Practice Act of Maine provides that the board of registration of medicine may revoke a license of any person, to whom a certificate has been issued by them, "after a conviction before a proper court, for crime in the course of professional business." The plaintiff, Donnell, a licensed physician, was indicted and tried for manslaughter. The verdict of the trial jury was "guilty," and after a motion for a new trial had been overruled, he appealed. Thereafter the board of registration of medicine, pending the appeal, after notice and hearing, revoked the certificate and canceled his registration. On a petition for a writ of certiorari to the Supreme Judicial Court of Maine, Donnell contended that he had not been "convicted" within the meaning of the section of the medical practice act quoted; that the return of a verdict of guilty is not the "conviction" which by the statute is a prerequisite to revocation of his certificate. With this contention the Supreme Judicial Court agreed, and quoted as follows from *Munkley v. Hoyt,* 179 Mass. 108, 60 N. E. 413, 414:

> We are of the opinion that the accused stands before the board of pharmacy exactly as before the court where his guilt has been established by his plea or by a verdict of a jury. If in that court his case is ripe for sentence, it must be considered as ripe for sentence before the board. It is the intention of the statute to give a pharmacist charged with a crime the right to a trial in the court having jurisdiction of his offense; but, if his guilt be there established, so that the court may impose sentence according to its powers, then it is sufficiently established for the board of pharmacy to act upon their finding, and to impose the penalty according to their powers.

In the present case, the court said, an issue "remains to be determined"; the case is not "ripe for sentence." The end of a criminal case is not reached when an appeal follows verdict; the case is pending, notwithstanding verdict and sentence. It goes without saying that the "determination" of the case on appeal may not end it. A new trial may be granted. The indictment, in that event, remains, and on the grave charges thereunder another trial must speedily follow, in the course of which the court must instruct the jury that the presumption of innocence, at the threshold of trial, protects the defendant. The Supreme Judicial Court held therefore that, pending the outcome of the appeal, Donnell had not been "convicted" within the meaning of the medical practice act.

Employment of Nurse Under Compensation Act

(Ranney Rig Building Co. v. Givens (Okla.), 285 P. 23)

March 7, 1924, one McFadden, in the course of his employment with the Ranney Rig Building Company, accidentally suffered a broken back, causing paralysis of his arms and of parts below. The company had him placed in a hospital, in the care of a Dr. McElroy. A sister of McFadden requested that he be sent to the home of his parents in another state. Dr. McElroy acquiesced in his removal, on condition that a nurse make the trip with him. Under the direction of the physician, and without consulting the employer, the hospital secured a nurse, a Miss Givens, who accompanied McFadden on his trip and attended him from May 12, 1924, to Aug. 27, 1924. The nurse was awarded $540, or $5 a day, for her services by the state industrial commission and the company appealed to the Supreme Court of Oklahoma. It was admitted that $5 a day was a reasonable charge for the services of the nurse and was the amount the company would have been required to pay had McFadden remained at the hospital. The company contended, however, that no person could recover for medical services, in a compensation case, rendered without the direct authority of the employer or the insurance carrier, where proper medical and hospital services were already being supplied. In support of this contention the company cited the section in the workmen's compensation act to the effect that an employee has the right to procure medical services on his own initiative only where an emergency exists immediately after the accident or where an employer has refused or neglected to supply such services. At the time of McFadden's removal, the court said, the company admitted the necessity of medical attention for him and the evidence was sufficient to show that Dr. McElroy concurred in the employment of the nurse. McFadden was placed in charge of Dr. McElroy by the employer and the physical condition of McFadden, being such that he was unable to feed himself or to move his hands or legs, and the fact that he had to be catheterized every two or three hours, indicated that a nurse was necessary. Although no direct authority was given to Dr. McElroy to employ the nurse, the court said, we think his authority under the circumstances would be implied.

The company contended, finally, that the nurse had no legal right to collect for services rendered after sixty days from the injury, unless there had been an application to the industrial commission for an order for further medical aid. Under the facts in this case, the court said, we cannot see the necessity of a determination by the commission. The whole record discloses that there was no dispute between the parties as to the necessity of medical and nurse's services after the sixty day period. At the time of the removal of McFadden from the hospital, the sixty day period had already expired and the need for further treatment was fully recognized by the company as well as by the physician. Under such circumstances, the court thought it would be entirely unnecessary to make an application to the industrial commission to determine whether or not medical aid was needed further.

Having found no error in the record, the Supreme Court affirmed the award of the industrial commission.

Hospital: Liability for Injury to Special Nurse.—A private nurse engaged in work in a hospital in the employ of a patient is an invitee of the hospital and the hospital owes a duty to such nurse to have its premises in a reasonably safe condition and to give warning of latent or concealed perils. There is no liability, however, for injuries from dangers that are obvious, which are as well known to the nurse as to the hospital. If, therefore, a special nurse is injured by reason of slipping on a floor, the hospital is not liable where the nurse knew of the slippery condition of the floor and continued to walk on it.—*Mautino v. Sutter Hospital Ass'n. (Calif.) 28 P. 369.*

Privileged Communications: Physicians May Be Compelled to Testify Under Common Law Rule.—In most jurisdictions, communications between a physician and his patient arising from the professional relations are deemed of such confidential nature that the hands of justice do not demand disclosure and statutes have been enacted excluding them as evidence on objection. At common law, however, there was no such privilage and, in the absence of statute, such evidence is competent and a physician may be compelled to testify.—*Louisville & N. R. Co. v. Crockett's Adm'x. (Ky.), 24 S. W. (2d) 580.*

Society Proceedings

COMING MEETINGS

American Society of Tropical Medicine, Cleveland, December 27-30. Dr. Edwin Peterson, U. S. Naval Hospital, Washington, D. C., Secretary.
American Student Health Association, New York City, December 29-30. Dr. D. F. Smiley, Cornell University, Ithaca, N. Y., Secretary.
Society of American Bacteriologists, Boston, December 29-31. Dr. James M. Sherman, Cornell University, Ithaca, New York, Secretary.
Southern Surgical Association, Lexington, Ky., December 9-12. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal Diseases of Children, Chicago

40: 705-940 (Oct.) 1930

*Alkalosis of Vomiting and Acidosis of Advanced Renal Disease. T. G. H. Drake, P. Marsh and J. L. Gamble, Boston.—p. 705.
*Effects of Insulin and Epinephrine on Blood Acetone in Fasting Children. L. Salomonsen, Oslo, Norway.—p. 718.
*Physiologic Variations in Inorganic Blood Phosphorus Content at Different Age Periods. J. K. Bullock, New Orleans.—p. 725.
*Cerebrospinal Fluid of Premature Infants. J. Glaser, Rochester, N. Y. —p. 741.
*Suspected Juvenile Tuberculosis. F. Eberson, J. P. Delprat and E. Wolff, San Francisco.—p. 753.
*Immunity: II. Effect on Skin Tuberculin Reaction of Nonspecific Factors. B. Eddy and A. G. Mitchell, Cincinnati.—p. 771.
Intubation Under Control of Sight. A. F. Pushkin, Leningrad, U. S. S. R. —p. 776.
Optimum Conditions for Precipitation of Casein from Human and from Cow's Milk. C. C. Wang and A. A. Wood, Chicago.—p. 787.
*New Cereal Mixture Containing Vitamins and Mineral Elements. F. F. Tisdall, T. G. H. Drake and A. Brown, Toronto, Canada.—p. 791.
Photosensitivation. C. B. Strauch, Milwaukee.—p. 800.
Bone Suppuration and Renal Calculi in Children. M. C. Borman, Milwaukee.—p. 804.
Hyperplasia of Corpora Adiposa Buccarum in New-Born Infant. F. C. Neff and J. A. Billingsley, Kansas City, Mo.—p. 813.
Psychiatric Aspects of Enuresis. F. N. Anderson, Los Angeles.—p. 818.
Geronimo Soriano, 1575—?. J. Ruhräh, Baltimore.—p. 851.

Alkalosis of Vomiting and Acidosis of Advanced Renal Disease.—The data presented by Drake et al. show the changes in the ionic composition of the blood plasma produced by continued vomiting and those found in the presence of advanced renal disease. The extent of repair obtained by the subcutaneous and intravenous injection of water and the substances indicated is also recorded by means of direct measurements of the chief factors of plasma structure.

Effect of Insulin and Epinephrine on Blood Acetone in Fasting Children.—In fasting children less than 3 years of age, an investigation was made by Salomonsen on the effect of insulin and epinephrine on blood sugar, on blood acetone and on the content of fatty acids in the blood plasma during the hours immediately following the injections. In eight experiments it was found that insulin reduces the blood acetone, but in decreasing degree according to the decrease of sugar in the organism. Epinephrine under the same conditions produces an increase in the blood acetone, the increase being greater in proportion as the organism is more poorly supplied with sugar. In one experiment, insulin effected a distinct decrease in the content of fatty acids in the blood. In five of six experiments, injection of epinephrine was followed by a rise in the quantity of fatty acids.

Inorganic Blood Phosphorus Content at Different Age Periods.—It would seem reasonably certain from the results reported by Bullock that there is a significant relationship between the high phosphorus levels and the age periods of most active growth.

Cerebrospinal Fluid of Premature Infants.—Evidence is advanced by Glaser in support of a theory that physiologic xanthochromia of the premature new-born infant, and probably of all new-born infants, occurs because of anatomic and physiologic immaturity of the blood-cerebrospinal fluid barrier. A case of primary pneumococcus meningitis is reported in a premature infant aged 8 days. A theory is offered to explain the paroxysmal or intermittent cyanosis occurring in premature infants with subtentorial meningeal hemorrhage on the basis of intermittent pressure by blood clot on the medulla oblongata. A chart is shown, illustrating the relationship between the icterus index of the blood serum and the icterus index of the cerebrospinal fluid. This curve reaches its peak during the second and third weeks of life.

Suspected Juvenile Tuberculosis.—A clinical and roentgen study of 306 cases of suspected juvenile tuberculosis has been made by Eberson et al. with especial reference to the evaluation of nine clinical symptoms, ten clinical signs, nine roentgen observations and the tuberculin test. The data were subjected to exhaustive statistical analysis. Evidence presented shows that commonly accepted clinical symptoms and signs have no diagnostic significance unless these are definitely correlated with positive tuberculin tests and roentgen observations that are positive for tuberculosis.

Skin Tuberculin Reaction of Nonspecific Factors.—As a result of two years' study in which several thousand tuberculin tests were performed, Eddy and Mitchell believe the conclusion warranted that there is often a depression of skin response to tuberculin in acute diseases. During the acute stage of such diseases as measles, diphtheria, scarlet fever and other acute conditions accompanied by febrile reactions, the tuberculin test which had previously been positive may become negative, returning to positive again during convalescence. This is shown by the fact that eleven of sixteen children who were known to have positive tuberculin reactions had no skin response to tuberculin during acute febrile illness. It is further supported by the fact that, of 159 children who had positive tuberculin reactions during convalescence from acute diseases, only 49 had positive tests during the febrile stage of these diseases. The depression of skin response does not seem to be peculiar to any disease or diseases but depends rather on the severity and the fact that there is a febrile state present.

Cereal Mixture Containing Vitamins and Mineral Elements.—The cereal combination devised by Tisdall et al., in addition to supplying calories, furnishes minerals and vitamins in appreciable amounts. It consists of wheat meal (farina), 53 per cent; oat meal, 18 per cent; corn meal, 10 per cent; wheat germ, 15 per cent; bone meal, 2 per cent; dried brewers' yeast, 1 per cent, and alfalfa, 1 per cent. It resembles the ordinary finely milled part grain cereals in that it is very palatable and does not produce a laxative or irritating effect on the intestinal tract. After the ingredients are ground, mixed and dried at a temperature of 70 C. for thirty minutes, the mixture will keep indefinitely. The minerals are obtained chiefly from the bone meal, wheat germ and alfalfa. One hundred grams (3½ ounces) of cereal contain as much calcium as 22 ounces of milk. The iron content is almost twice that of egg yolk, our highest source of iron in food. Copper is present in good concentration, 1.3 mg. per hundred grams of cereal. As the average infant and child consumes from 1 to 2 ounces of dry cereal a day, the calcium in this amount of cereal mixture is equivalent to that contained in from 6 to 12 ounces of milk. The amount of iron in 1 ounce of dry cereal mixture is slightly greater than the amount contained in two egg yolks. The cereal mixture has been used almost exclusively for the past three months in the Hospital for Sick Children, an institution with more than 300 beds. It has been found to be just as palatable as any of the finely milled cereals at present so widely used.

American Jour. Obstet. & Gynecology, St. Louis

20: 441-594 (Oct.) 1930

Postsalpingectomy Endometriosis (Endosalpingiosis). J. A. Sampson, Albany, N. Y.—p. 443.
*Ovarian and Pituitary Changes Associated with Hydatidiform Mole and Chorio-Epithelioma. E. Novak and A. K. Koff, Baltimore.—p. 481.

Question of Possible Endometrial Trauma and Dislocation Associating Uterotubal Insufflation. I. C. Rubin, New York.—p. 519.
*Postoperative Obstetric Embolus: Incidence, Cause and Prevention. J. O. Polak and V. Mazzola, New York.—p. 529.
Fetal Malformations in Multiple Pregnancy. F. L. Adair, Chicago.——p. 539.
*Granulosal-Cell Tumors of Ovary and Relation to Postmenopausal Bleeding. R. W. Te Linde, Baltimore.—p. 552.
Early Diagnosis of Adnexal Cancer. B. M. Anspach, Philadelphia.—p. 571.
Treatment of Salpingitis by Local Injection of Turpentine. H. M. Little, Montreal.—p. 582.

Ovarian and Pituitary Changes Associated with Hydatidiform Mole and Chorio-Epithelioma.—Novak and Koff made a study of two cases of hydatidiform mole and two of chorio-epithelioma, in all of which the ovaries were available for study, while in one of the cases of chorio-epithelioma a histologic study of the pituitary was also possible. Histologic studies, such as those included in this report, and also the biochemical studies which have been described by a number of authors, leave little doubt that the anterior pituitary is the immediate cause of the lutein hyperreaction seen in the ovaries of such cases. These studies indicate that the hyperluteinization involves both the granulosa and the theca interna. The histologic study of the anterior pituitary in one of the cases of chorio-epithelioma showed an abnormally marked and persisting pregnancy reaction. This observation, for the first time, offers a histologic explanation for the persistence of the pregnancy test long after removal of the primary tumor, as has been reported by two or three recent authors. This abnormally persistent pregnancy reaction in the pituitary, with the persistence of the pregnancy test, is believed to be due to the presence of considerable masses of trophoblastic tissue in the metastases, as was almost certainly the case in this patient. In short, the evidence indicates that the interreaction is a triangular one, the trophoblastic increase being responsible for the pituitary reaction, and the latter, in turn, calling forth the abnormal ovarian response.

Postoperative Obstetric Embolus.—The total incidence of thrombosis and embolism in 12,000 gynecologic and obstetric cases was found by Polak and Mazzola to be 0.5 per cent. The number of thromboses in the obstetric group is double the number in the gynecologic. Embolism predominates after gynecologic operations, thrombosis in obstetric deliveries. Thrombosis following operation is more liable to cause embolism than when it occurs following delivery. Emboli following operation are more fatal than those following delivery. The appearance of the clinical symptoms of thrombosis and embolism usually occurs between the second and third weeks, about the time when patients are allowed out of bed. Mortality rate is higher in patients more than 40 years of age. In the series the number of patients more than 40 years of age is greater in the gynecologic group. Morbidity was found to be present in 100 per cent of cases; infection is therefore a factor that must be considered. Obesity, hypotension, leukopenia, albuminuria, pregnancy, age, fibroids, anemia, toxemia—all predispose to venous stasis. Experimentally, torsion leads to varicosities, stasis and thrombosis with a generalized hyperplasia and hypertrophy of all contiguous tissues.

Granulosal-Cell Tumors of Ovary and Relation to Postmenopausal Bleeding.—Three cases of granulosal-cell tumor of the ovary and one of the closely related oophoroma folliculare are reported by Te Linde and described histologically. The histogenesis of granulosal-cell tumors is discussed. Evidence has been produced in the form of an extremely early tumor which would indicate that the probable origin is from embryonic rests of ovarian parenchyma in the medullary portion of the ovary. Clinically, the tumors occur most frequently after the cessation of the menses and are usually associated with bleeding. The importance of early diagnosis and operation is emphasized, particularly because the tumors are sufficiently benign to offer an excellent chance of surgical cure.

Diagnosis of Intracranial Tumors by Supravital Technic. L. Eisenhardt and H. Cushing, Boston.—p. 541.
*Small Cell Carcinomas of Lung. H. T. Karsner and O. Saphir, Cleveland.—p. 553.
*Skeletal Metastases in Carcinoma of Thyroid. I. Levin, New York.—p. 563.
*Multiple Gummas of Heart in New-Born. J. W. Williams, New Orleans.—p. 573.

Metastasizing Carcinoid Tumor of Jejunum.—A case of multiple carcinoid tumors of the jejunum, one of which caused intestinal obstruction, with metastases in the mesentery and liver, is reported by Gáspár. Histologic examination revealed the picture of typical carcinoid tumors. Serial sections definitely indicate that at least two of the tumors originated in the crypts of Lieberkühn. Positive silver impregnation of the tumor cells confirmed Masson's contention that the origin of carcinoid tumors is in the Nicholas-Kulchitzky-Masson cells in the glands of Lieberkühn.

Small Cell Carcinomas of Lung.—Karsner and Saphir base their discussion on twenty-five cases seen by them. They believe that small cell primary tumors of the lungs or bronchi are epithelial in character, as indicated by cell arrangement, relation of connective tissues and blood vessels, and complete absence of capacity to form reticulum. Small cell cancers of the lung originate in bronchi or bronchioles and are probably unicentric in origin. Small cell cancers of the lung more frequently produce large mediastinal masses than do other cancers of this organ and are firmer in consistency, but in other clinical and gross pathologic aspects they do not show distinctive characters.

Skeletal Metastases in Carcinoma of Thyroid.—Three cases of metastases in the skeleton secondary to carcinoma of the thyroid are reported by Levin. In all three cases the clinical symptom complex as well as the evident pathologic condition was caused by tumors in the bone. While the primary tumor in the thyroid was insignificant, both pathologically as well as clinically, compared with the condition in the skeleton, as a result in all three cases, the primary condition was overlooked. Levin urges that in a search for a primary malignant tumor, in a female, next to the breast, the thyroid must be thought of, and in a male, next to the prostate, the thyroid must be considered as the most probable seat of a primary tumor. Such a diagnostic analysis is of importance not only from the theoretical but also from the practical clinical standpoint.

Multiple Gummas of Heart in New-Born.—A case of gumma of the heart in a Negro infant that died a few hours after birth is reported by Williams. The term gumma as descriptive of the lesion is questioned since the microscopic picture is at variance with that of a gumma. The terms localized syphilitic cellulitis and fulminative syphilitic myositis are suggested in its stead as descriptive of this lesion since it is characterized by muscle destruction and infiltration with lymphocytes, polymorphonuclear leukocytes, monocytes and plasma cells.

Simultaneous Occurrence of Psychosis in All Members of Family Group. S. S. Cottrell and F. L. Vibber, Harding, Mass.—p. 287.

Boltz (A. A. S.) Test in Cerebrospinal Fluid.—Summing up the reports of clinical investigators, Walker and Sleeper found that: (1) Fluids from untreated patients with dementia paralytica give strongly positive Boltz reactions in about 95 per cent of all cases investigated; (2) positive reactions are obtained in many other conditions, whether or not syphilis is present; (3) in neurosyphilitic cases, treatment tends usually to reduce the intensity of the reaction, and (4) in cases in which protein has also been determined in the fluid, the intensity of the Boltz reaction varies with the protein content. It is obvious that the Boltz reaction is not in any way specifically diagnostic for neurosyphilis. As a means of rapidly estimating the amount of protein in the spinal fluid, either as a diagnostic aid or as a guide in treatment, it seems to have a definite and valuable use. It is extremely doubtful whether the test can ever be made really quantitative even by the use of color standards and controlled time and temperature. The color is transient, the reagent (glyoxylic acid) is unstable, and the test is apparently subject to interference from other substances in the fluid; e. g., excess of dextrose. The Boltz reaction cannot be said to replace in any way the longer and more elaborate methods for the exact determination of protein in the spinal fluid, but when there is not time or when equipment for such tests is lacking it may well serve as a convenient and practical approximation.

Spinal Drainage in Alcoholic Deliria.—Goldsmith asserts that spinal drainage is an effective means of treatment in acute alcoholic delirium states, attended by few sequelae, and the length of stay in the hospital of patient suffering with these conditions has been materially reduced in 78 per cent of the cases to an average stay of but thirty days. The treatment, however, is most effective when instituted within twenty-four hours following admission to the hospital. No after-treatment is necessary in the great majority of cases. These patients convalesced rapidly under the routine hospital care.

Carcinoma of Cervix Uteri: Occurrence in Early Life. C. H Lupton, Norfolk, Va.—p. 150.

Surgery of Sympathetic Nervous System.—Fourteen cases of sympathetic ganglionectomy are reported by Flothow. In seven cases dorsal ganglionectomy was done, the removal of the second rib and transverse process being used as the approach. In the other seven cases the lumbar ganglions were removed through a transabdominal approach. Four lumbar ganglionectomies for chronic polyarthritis resulted in relief of pain and marked progressive improvement in joint function. Three ganglionectomies for Buerger's disease with vasospasm of the second dorsal and first lumbar are reported. Two cases of amputation pains and one of brachial plexus avulsion are reported in which dorsal ganglionectomy gave some relief. Two cases of dorsal ganglionectomy for painful conditions of the face are reported. One patient with trifacial neuralgia with recurrence of pain after severing of the sensory root has had complete relief for one year. A case of atypical pain in the face gave inconclusive results. One patient with megacolon and one with spastic colon were relieved by lumbar ganglionectomy.

Lead Poisoning and Eighteenth Amendment.—Moore suggests that a more extensive search for lead as an etiologic factor in many of the so-called scofflaws who are suffering from symptoms of peptic ulcer and enteritis might increase the incidence of lead poisoning.

Roentgen Significance of Gas Under Diaphragm.—The case reported by Jenkinson and Ellis is of importance from a diagnostic standpoint. The value of a definite roentgen finding was questioned and even following a laparotomy was thought to be misleading. At the operation the surgeon found nothing to account for the gas under the diaphragm. There was no history or evidence of an injury to the chest, abdomen or pelvis. There was no chance of the air being secondary to a fractured rib or to a penetrating wound of the abdomen. There had been no paracentesis with the possibility of the diaphragm having been penetrated. As the patient was a male, the possibility of tubal insufflation can be ruled out. There had never been an attempt to produce a pneumoperitoneum. In view, therefore, of the history and physical observations, the possibility of the air having entered the peritoneal cavity from without can be ruled out.

Alcohol Injection of Nerve Roots for Thrombo-Angiitis Obliterans.—Blocking the right twelfth thoracic and the first and second lumbar nerve roots with alcohol definitely increased the circulation of the right lower extremity in three cases of thrombo-angiitis obliterans reported by Stern. This procedure blocks both the sympathetic fibers in the rami communicantes at these levels and the vasomotor fibers in the genitofemoral, femoral and part of the obturator nerves (somatic). These fibers innervate the aorta, common iliac, external iliac, femoral and popliteal arteries, and possibly other terminal arteries in the leg and foot. Blocking of somatic muscular and sensory branches of nerves arising from the twelfth thoracic and the first and second lumbar roots did not produce serious paresis or paralysis of any muscles, or any unbearable disturbance in the skin areas supplied by these nerves. The good results obtained from this procedure may be explained as being due to an increase in the circulation of the lower extremity, caused by the removal of an appreciable vasoconstriction status that exists in this disease in the diseased vessels themselves, in those not diseased, or in both diseased and nondiseased vessels.

Radical Treatment of Inguinal Hernia.—A technic is described by Soresi which exteriorizes the sac and any bulging peritoneum, and utilizes the sac as a reinforcing tissue to a weak region. By this technic, atrophy of the testicle, hematomas, and injury to the intestine, bladder, vas deferens and spermatic artery are completely prevented. Recurrences of indirect hernia become a physical impossibility. Recurrence of direct hernia is rendered more improbable because the blood, lymphatic and nerve supply of the region have not been damaged and the region is reinforced by the presence of the exteriorized sac. Trauma and shock, or any other postoperative complications, are reduced to a minimum, little damage being done to the tissues and a short time being required for the operation. In children and in young adults, the operation has been performed often in less than ten minutes and without even ligating a single blood vessel, when the diathermic scalpel was used. Numerous clinical results, including two cases of sliding hernia, one strangulated hernia and one with ectopic testicle, up to the present time are satisfactory.

Trendelenburg Operation for Pulmonary Embolism.—Nystrom states that with Trendelenburg's operation it seems that only in rare cases will it be possible to save a patient otherwise condemned because of pulmonary embolism. It is on the prevention of pulmonary thrombosis that hope has to be placed of being able to defeat at some future time one of the most distressing complications with which, after the victories won by the introduction of antiseptics, surgery has still to wrestle. He reports ten cases. It is of interest that a patient who has recovered from an operation for pulmonary embolism may not suffer any lasting inconvenience from the operation. Two patients who were cured have recently been examined and are in good health. The man works as a farmer and he says he is not as persevering as before his illness and with hard work he feels palpitation of the heart; but he has no shortness of breath from climbing hills and stairways, and he works the whole day. As a result of this thrombosis the legs are swollen in the evenings, but at the time of examination there was no edema. Beneath the weak part of the chest wall along the sternum there is a sharp systolic murmur, but nowhere else. The pulse is 60, the blood pressure 160 systolic. The woman says she is as persevering as before and never is conscious of her heart. The legs are a little swollen at times as a result of the thrombosis, but at the time of examination there was no edema. A sharp systolic murmur was heard under the weak part of the chest wall, but nowhere else. The pulse was 74, the systolic pressure 140. In both cases, roentgen examinations did not show changes that could be ascribed to the embolism.

Resection of Anterior Half of Pyloric Sphincter.—A corrective procedure which removed the pyloric interference with duodenal regurgitation has been applied by Deaver and Burden in clinical cases of peptic ulcer, pylorospasm and hyperchlorhydria. In this procedure the anterior half of the pyloric sphincter is removed. In an experience with eighty-one cases over a period of two and one-half years, the results have been at least as satisfactory as from any operation they have used in similar cases so far as symptomatic relief and postoperative roentgen observations are concerned. They have not yet encountered a recurrence of ulceration and, of course, the development of gastrojejunal ulcer is impossible. The removal of the anterior half of the pyloric sphincter is a much simpler operation than gastro-enterostomy or resection of the stomach, yet the results are equally satisfactory and the postoperative complications and late sequelae are much less hazardous.

Mortality in Operations for Gastric and Duodenal Ulcers.—A review of ten years' experience is presented by Horsley. He says that it seems probable that the vast majority of cases of peptic ulcer can be cured either by medical treatment consisting largely of regulation of diet, or by operation. After any stomach operation medical treatment, particularly regulation of the diet, should be carried out for at least several months. This is just as essential in a stomach that has been temporarily crippled by the operation, until it can recover its tone and function, as it is to use splints after an accurately set fracture until the bone itself has become strong. The kind of operation done should be suited to the type of lesion present. In a few patients, however, there seems to be an inherent tendency toward recurrence of a peptic ulcer even after multiple operations and careful medical treatment. Fortunately, they constitute a small percentage of the total number of patients with peptic ulcer. This group can usually be effectively managed along lines of rest for the stomach, such as feeding by jejunostomy for months or even permanently, as recommended by Balfour.

Mortality in Operations for Peptic Ulcer.—An analysis made by Gatewood of 163 patients treated by gastro-enterostomy between 1915 and 1925 shows a hospital mortality of 1.8 per cent with 82 per cent of the patients well or greatly improved. Of the remaining 16 per cent, 8.5 per cent died subsequently of some stomach condition and 4.8 per cent died of other causes. While the majority of this last group were undoubtedly well as far as stomach symptoms were concerned, they have not been included in the known cures. Considering that this report covers a selected group of patients, gastro-enterostomy seems to be a satisfactory operation in spite of the failures. Gastro-enterostomy for ulcer in the Presbyterian Hospital during the past fifteen years has been followed by a hospital mortality of 2.7 per cent. Acute perforations operated on within the first twelve hours carried a mortality of 5 per cent as compared with a total mortality of 20 per cent. Recurrence of symptoms demanding further surgery occurred in nearly all simple closures and the mortality does not seem to be increased by concomitant gastro-enterostomy. Gastric resection for gastric ulcer and gastro-jejunal ulcer is an operation that has increased in frequency during the past five years. Although the series is small (thirty) there are three known gastro-jejunal ulcers (10 per cent). The preoperative medical management of all cases for at least a short period before operation seems to be indicated from an analysis of the deaths in this series.

Results of Gastro-Enterostomy for Ulcer of Duodenum and Stomach.—Five hundred consecutive cases of duodenal ulcer in which gastro-enterostomy alone was done were studied by Balfour. From the standpoint of relief of symptoms, it was found that after operation 87 per cent of the patients obtained relief which they had been unable to obtain by any other means. In 69 per cent either the relief had been so complete that the patient had paid no attention to diet or to habits of living, or dyspepsia was so slight as to be readily controlled by simple measures. In 18 per cent the results could be classified as fair. In 13 per cent the patients did not obtain permanent relief from operation. The deaths within five years from all causes were twenty-one (4.28 per cent). In no case in the series, or in any other series studied, did perforation of the duodenal ulcer, either acute or subacute, occur after gastro-enterostomy had been done. In other words, satisfactory gastro-enterostomy apparently afforded absolute protection against this serious complication. In none of the cases in this group did obstruction of the pylorus develop following gastro-enterostomy. Forty-five of the 500 patients (9 per cent) had one or more hemorrhages after operation, but only 1 of the 500 died from hemorrhage. The study also confirmed the fact that such hemorrhages often are directly associated with unusual physical and mental strain, overloading the stomach, excessive use of tobacco and alcohol, and gross dietetic indiscretions and severe focal infection. No instance of carcinoma developing subsequent to operation was encountered. The protection afforded by gastro-enterostomy against the formation of a secondary chronic ulcer is approximately 96 per cent. Twenty patients had recurrent ulceration (4.07 per cent of 491 cases), and of these gastrojejunal or jejunal ulcer was listed in sixteen cases, a total percentage of 3.25 occurring in a period of ten years or more after operation. One hundred cases were studied in which gastro-enterostomy alone was done for gastric ulcer. The operative mortality in this series was 3 per cent. Seventy-nine per cent of the patients, five years or more after operation, were relieved. In 50 per cent the relief had been complete; in 29 per cent slight and easily controlled symptoms occasionally occurred, the patient considering the results of operation as good. In 4 per cent the result was classified as fair; in 17 per cent the result was poor. Gastro-enterostomy affords almost complete protection against the complications of perforation and obstruction. The subsequent deaths from all causes in this group during five years after operation were seventeen. The protection against recurrence or reactivation of ulcer afforded by gastro-enterostomy alone for gastric ulcer is approximately 96.9 per cent. It is a significant fact that gastrojejunal ulcer is not a problem in the treatment of gastric ulcer since the complication did not occur in this group. In cases in which the operation of choice, namely, excision and gastro-enterostomy, is possible, gastrojejunal ulceration is almost unknown. The striking fact in the study of this series of 100 cases is that an indirect operation alone for gastric ulcer can be depended on to give a high percentage of good results in cases in which the removal of the lesion, by any method, is difficult, and partial gastrectomy is associated with prohibitive operative risk and an unwarranted sacrifice of the stomach.

Results of Operations for Excision of Ulcer of Duodenum.—This report by Judd and Hazeltine covers 1,363 cases with a mortality of 0.44 per cent. The ultimate results in this group of cases are practically the same as the ultimate results obtained by gastro-enterostomy; 90 per cent of the patients have obtained satisfactory results.

Results After Operations for Gastric and Duodenal Ulcers.—Bloodgood urges the more frequent choice of the first Billroth anastomosis after resection of the stomach, pylorus or duodenum. In resection for cancer, it is unnecessary to give the wide margin of an uninvolved wall. When the second Billroth procedure must be adopted, he urges a long-loop gastro-enterostomy and recommends Balfour's modification of Polya's operation. In duodenal ulcer the Finney pyloroplasty is the operation of choice, if local conditions allow it, with and without the local excision of the ulcer. When Finney pyloroplasty is contraindicated, there must be a choice between short-loop posterior gastro-enterostomy and resection. In large chronic ulcers of the duodenum, especially those adherent to the pancreas, Bloodgood advises resection rather than posterior gastro-enterostomy. Finney's pyloroplasty or any type of gastroduodenostomy with local resection of the ulcer may be carried too far. In such cases either a posterior gastro-enterostomy, resection and the first Billroth procedure should be the operation of choice. It is rarely necessary when operating for a perforated duodenal ulcer to do more than to close the perforation and drain. A diagnosis of inoperable carcinoma should not be based on palpation and roentgen examination alone. The patient should be given the benefit of exploration unless there are skin metastases or fluid is present in the peritoneal cavity. And even then, if there is obstruction, operation is indicated.

Surgical Therapy for Gastric and Duodenal Ulcer.—Four hundred and thirty-five cases of ulcer, treated surgically, have been reviewed by St. John. Gastro-enterostomy was performed in 119 cases and partial gastrectomy in 76 cases. He has established the presence of marginal ulcer in 6.9 per cent of the gastro-enterostomies and in 3.6 per cent of the resections performed in his own clinic. The mortality of gastro-enterostomy was 15.1 per cent; mortality due to technical error, 5.9 per cent; the mortality of partial gastrectomy was 19.6 per cent; mortality due to technical error, 15.8 per cent.

Peptic Ulcer Surgical Aspects Including End-Results.—The efficiency and reliability of roentgen diagnosis of peptic ulcer has been confirmed in the series of cases analyzed by Hartwell and Felter in which the preoperative and operative observations have been compared. Gastro-enterostomy has been shown to be a safe procedure with a mortality of 2.1 per cent in the hands of many different surgeons. It is likewise excellent from a therapeutic standpoint with 92 per cent of satisfactory results. The location of the gastrojejunostomy opening does not seem to influence greatly the clinical and mechanical results of operation. Polya resection seems to be the best procedure in gastric ulcer and has given uniformly good results in this small series, but mortality is high. These cases demonstrate the almost uniformly good results of operation for peptic ulcer in the hands of a comparatively large group of surgeons.

Operations for Gastric and Duodenal Ulcer and Causes.—In considering the mortality and the postoperative complications in his series of 267 cases, Gibbon says it is apparent that some form of disease in the lung is most conspicuous. In the clean cases, wound infections and peritonitis have not been high and there was but one fatal hemorrhage—a case of gastrectomy.

Results of Operations for Chronic Gastric and Duodenal Ulceration.—Finney and Hanrahan analyze 737 cases of ulcer of the stomach and duodenum in which operation was performed. One hundred and ten operations were performed after perforation, with an operative mortality of 23.6 per cent. The mortality in all operations for chronic ulcer was 8.6 per cent. Of the chronic ulcers, 268 were gastric and 339 duodenal. There were twenty operations for postoperative marginal ulcer in the chronic group. The operations included such miscellaneous procedures as excisions, with knife or cautery, wedge and sleeve resections, either with or without a gastro-enterostomy, simple gastro-enterostomy, pyloroplasty, with or without excision, and partial gastrectomy. The miscellaneous procedures were applied to those cases in which pyloroplasty or gastro-enterostomy were for some reason contraindicated. Pyloroplasty was the operation of choice for ulcers of the duodenum, pylorus or antrum, when the ulcer could be included in the pyloroplastic incision and when the duodenum could be satisfactorily mobilized. Partial gastrectomy was occasionally used for duodenal ulcer and more commonly for ulcers of the body of the stomach, when conditions warranted the more radical procedure. Gastro-enterostomy was used for ulcers of the lesser curvature and fundus when partial gastrectomy was not practicable, and for ulcers of the pylorus and duodenum when difficult mobilization or the presence of excessive scar tissue precluded pyloroplasty. The operative mortality for this series approximated that of most hospital series covering similar periods and performed under similar circumstances. The figures by operations are as follows: miscellaneous operations of expediency, 26.9 per cent; gastro-enterostomy, 8.1 per cent; pyloroplasty, 5.2 per cent, and partial gastrectomy, 12.9 per cent. The operative mortality in eighty-four cases of gastro-enterostomy in the Johns Hopkins Hospital between 1925 and 1930 was 2.4 per cent. The operative mortality following pyloroplasty for duodenal ulcer was 2.7 per cent. These operations were done by men of varying experience, from assistants in training to older experienced surgeons. The end-results of these operations also correspond closely to those of most similar series, 85.6 per cent benefited by the operation. Duodenal ulcer yielded better results than gastric, even after allowance is made for those patients with gastric ulcer known to have died later of carcinoma.

Biliary Fistulas Following Cholecystectomy.—The surgical demonstration of inadequate spontaneous internal biliary fistulas between the hepatic duct and the duodenum or stomach above strictures of the hepatic duct after cholecystectomy is reported by Lahey. The spontaneous closure and entrance of bile into the intestinal tract from complete external biliary fistulas is reported, as is the satisfactory progress of these cases over a period of three and twelve months, respectively. The possibility of destruction of the preliminary complete external biliary fistulas by the occurrence of inadequate spontaneous internal biliary fistulas, together with a report of such an occurrence twice in the same individual, is reported and a plan to prevent it is proposed.

Cancer of Buccal Mucosa.—The results of treatment of carcinoma of the mouth by surgery and irradiation are compared by Simmons. In primary cases without clinical evidence of metastases, surgical treatment offers 40 per cent chance of a five-year cure as against 8.5 per cent by irradiation. In primary cases with clinical evidence of metastases, irradiation offers no chance of permanent cure, and operative treatment 30 per cent. These figures are hardly fair, however, as only the most favorable cases were submitted to surgical treatment. On the other hand, no cases were cured by irradiation. Postoperative prophylactic roentgen treatment had no effect in preventing recurrence. Of the primary cases fatal because of recurrence, life was prolonged by treatment, but life is longer following surgical treatment than irradiation. In the recurrent cases in which death occurs because of disease and in inoperable cases, life is distinctly prolonged by irradiation.

Ileocecal Obstruction Associated with Appendicitis.—Speese and Bothe assert that a certain proportion of the poor remote results in operations for chronic appendicitis may be attributed to failure to note ileocecal obstruction and to relieve it properly. Relief obtained by freeing adhesions followed by the use of omental transplants has afforded sufficiently favorable results in overcoming the obstruction to justify the employment of this proceedure.

Ulceration of Abdominal Skin and Subcutaneous Tissues Following Operation.—A rare wound-infection is described by Freeman, occurring principally, but not always, in connection with abdominal incisions. It begins usually in a stitch-hole a number of days following an operation and spreads slowly and indefinitely, causing marked induration of the skin, which is at first red, then livid and finally gangrenous. The process is accompanied by intense pain and tenderness and moderate fever, and may last for weeks or months, causing great physical and nervous exhaustion and possibly resulting in death. The cause is obscure, although an ameba has been suggested by Cole and Heideman, and the symbiotic action of a streptococcus and a staphylococcus by Brewer and Meleny. It usually has been found in connection with suppurating wounds, but in Freeman's case it began in a stitch-hole, following primary union of a gallbladder incision without drainage. All ordinary methods of treatment usually have failed, the only effective remedy being the heroic use of the actual cautery.

Nonoperative Treatment of Tuberculous Joints.—Lo Grasso postulates that tuberculosis is a systemic, not a local, disease, irrespective of the particular local manifestations that may be present. A patient with a tuberculous joint should be treated for the systemic infection and the joint treated as a complication, not as the primary infection. Operative procedure is likely to disseminate the disease, especially if undertaken during the acute stage. If surgery must be resorted to, it should be done only after a preliminary course of conservative treatment so as to bring the resistance of the patient to a maximum. Experience has shown that such conservative treatment usually results in healing with useful motion, and retention of that motion without recurrence of the disease.

Repair of Bone in Presence of Aseptic Necrosis.—Phemister states that aseptic necrotic bone in continuity with living bone is gradually invaded and more or less completely replaced by new bone through the process of creeping substitution, unless it is too inaccessible and is broken down by traumatism. In these diseases there is a marked fibroblastic and fixed tissue phagocytic reaction and, in rare cases, an infiltrative reaction which result in absorption of necrotic bone without bony replacement by creeping substitution except in occasional instances. New bone formed from surviving osteogenic elements replaces more or less completely the absorptive tissues in the course of time.

Calf-Milt Diet in Treatment of Suppurative Tuberculosis of Joints.—The spleen has a markedly beneficial influence on tuberculosis by producing antibodies and increasing the resistance of the diseased tissue. Fliegel has found that the calf appears to exert a decided influence on human tuberculosis. The active substance of the spleen is not as yet known. Therefore, the calf spleen is given either raw or rare, in order not to destroy the active substance. The course consists of daily doses of from 50 to 100 Gm. for four weeks, followed by intermission of two weeks. It may be necessary to repeat this administration several times. The improvement in a great number of cases is striking, especially the improvement of the general condition. The milt diet is harmless and should be tried in all severe cases.

Early Phases of Bone Repair.—Ham made a histologic study of a series of experimental fractures produced in the rabbit in his endeavor to determine the origin, nature, and growth of the cells that repair a fracture, and a study of some of the purely local factors that influence the process. The adult bone cell is distinguished from the osteogenic cell that is found lining the bone in the periosteum, the haversian canals and the endosteum. The adult bone cell was found to take no active part in the process of regeneration of bone following a fracture. The osteogenic cells proliferate and differentiate into bone and cartilage. Concerning the controversy regarding the existence of a specific osteogenic cell, the subject of metaplastic bone formation is reviewed. The usual method of bone repair is through the agency of these specific osteogenic cells and not by the metaplasia of fibroblasts. Two factors, the presence of a local deposit of calcium salt and a good blood supply, are of great importance in effecting the differentiation of the osteogenic cell into bone. Cartilage results from the growth of osteogenic cells in the absence of these two factors. In the repair of fractures, bone and cartilage formation result from the differentiation of osteogenic cells in different environments.

Operation for Cure of Paralytic Genu Recurvatum.—The operation described by Mayer is intended to create an adequate bone block so attached to the tibia as to correspond to the olecranon process of the ulna—in other words, to make an elbow joint out of the knee. Severe grades of genu recurvatum can be successfully treated by inserting a bone graft into the upper end of the tibia. The graft, fusing with the tibia and the patella, forms a bone block that effectually prevents hyperextension. Great care must be taken not to maintain the overcorrected position too long, since otherwise a flexion contracture is likely to ensue.

End-Results of Synovectomy of Knee.—Boon-Itt avers that in well selected cases of chronic arthritis of the polyarticular type about 60 per cent of the cases are benefited by synovectomy, while in the monarticular type about 75 per cent of the cases are improved by the operation. Traumatic arthritis has a high percentage of good results (95 per cent) after synovectomy. Tuberculous arthritis of the knee does not obtain relief from synovectomy.

Effect of Lumbar Sympathectomy on Growth of Legs Shortened from Anterior Poliomyelitis.—Harris cites cases to demonstrate that lumbar sympathectomy performed on patients suffering from paralysis of the leg due to anterior poliomyelitis produces the same vascular changes that have been observed in normal patients; namely, increased warmth and dryness of the foot due to vasodilatation and to paralysis of the sweat glands. The calorimetric readings indicate that sympathectomy causes considerable increase in the blood supply to the foot. The vascular changes are of prolonged duration and perhaps are permanent. It is possible to accelerate the rate of growth of a child's leg by the operation of lumbar sympathectomy. The increase in comfort that results from transforming the cold, blue, damp foot of anterior poliomyelitis to one that is warm and dry is much appreciated by the patient.

Surgical Treatment of Congenital Anterior Dislocation of Knee.—Kofman describes the operation performed by him in these cases as applied in one case as follows: The tibial tubercle was chiseled off, and the patella and its tendon were turned proximally. The iliotibial band was divided from 3 to 4 cm. above the joint line and freed from the adjacent muscles. By powerful traction the articular surface of the tibia was brought down to the normal level but, because of distortion of the joint surfaces, could not be maintained in position even after division of the tense cruciate ligaments. To improve the contact, several thin transverse slices were removed from under the cartilage of the tibial head, until the joint surfaces could be well approximated. The patellar ligament was then too short, so the tibial tubercle was freed from its periosteum and the latter sewed to the tibia 3 cm. proximal to its former position. The wound was closed and a cast applied with the knee in extension.

So-Called Renal Rickets.—A case is described by Swart in which marked bony deformity, of the type of osteomalacia, was associated with definite renal insufficiency in a youth, aged 18 years.

Congenital Deformity of Hand Combined with Supernumerary Toes.—The malformation of the hand in Cooperman's case was caused by fusion of a supernumerary metacarpal to the lateral ulnar margin of the fifth metacarpal. This deformity was unsightly and interfered with the normal function of the hand. The patient also presented a supernumerary sixth toe on each foot. Favorable results followed operation.

Second Attacks of Acute Poliomyelitis.—Still found only eight recorded cases in which there seemed to be a clear history of a second attack of acute poliomyelitis. He adds one case.

Spontaneous Nystagmus in Congenital Syphilis.—Asherson concludes from his study of eight cases that nystagmus, as tested for in the usual manner, is a not uncommon concomitant of hereditary syphilis, among treated cases in infants and children, although a true Hennebert's phenomenon was not demonstrated in any of these cases.

Tonsils and Nasopharyngeal Epidemics.—Bradley has made an attempt to assess the value of the tonsil-adenoid operation in the prevention of epidemic nasopharyngeal infections. The operation was found to be of no appreciable value, but some evidence is produced to show that it is followed by compensatory hypertrophy of other lymphoid tissue in the presence of acute disease of the upper air passages. The conditions found suggest that, until the loss of lymphoid tissue is made good, patients who have been operated on are more susceptible to the common catarrhs and more frequently attacked by complications. Chronic tonsillitis is a complication of acute nasopharyngitis. Autogenous reinfection from septic tonsils is not common. It is discussed and the necessity for operation in these circumstances emphasized. A distinctive type of epidemic sore throat is described. A tentative statistical proof that coryza and febricula are "formes frustes" of the stationary fevers of a community is presented.

Meningeal Hemorrhage in New-Born.—One hundred and three cases of intracranial hemorrhage occurring at birth are discussed by Fleming and Morton. The immediate mortality was 48 per cent. The mortality in the premature infants was 75 per cent. Labor was abnormal in half the cases. Tentorial tears were the most common postmortem finding. In thirty-three patients seen when over a year old, five were found to have mental or physical defects. Many of the infants showing severe injury to the head at birth made perfect recoveries and showed no sequelae. A xanthochromatic cerebrospinal fluid found by lumbar puncture is the most certain proof of meningeal hemorrhage in the new-born.

Results Following Sympathetic Ramisection.—Royle has performed the operation of sympathetic ramisection approximately *600 times with 3 deaths. Two of the deaths were from* embolus shortly after the operation, and one was from pneumonia in the first week following operation. Thus the operative death rate is 0.5 per cent. Approximately 300 patients underwent operation, and 2 operations were performed on each patient. In some instances all four limbs were deprived of their sympathetic nerve supply. In the case of the upper limb, it is interesting to note, a sympathetic trunk resection performed bilaterally in the upper thoracic region has not apparently a detrimental effect on the cardiac mechanism. Many patients were able to play vigorous games after the operation without discomfort. To ascertain the effect of operative treatment in spastic paralysis and allied conditions, he sent a questionnaire to each of his patients and received 126 replies. His records show that the remainder of the patients who did not reply had similar if not better results. Congenital spastic paraplegia: excellent, 21.62 per cent; good, 54.05 per cent; poor, 13.51 per cent, and no result at all, 10.8 per cent. Congenital spastic hemiplegia: excellent, 31.42 per cent; good, 40 per cent; poor, 25.71 per cent, and no result at all, 2.85 per cent. Congenital spastic chorea: excellent, 30 per cent; good, 40 per cent; poor, 30 per cent. Acquired spastic hemiplegia: excellent, 21.5 per cent; good, 36.8 per cent; poor, 36.8 per cent, and no result at all, 5.2 per cent. Acquired spastic paraplegia: excellent, 50 per cent; good, 50 per cent. Parkinsonian rigidity: excellent, 4.5 per cent; good, 22.7 per cent; poor, 40.76 per cent, and no result at all, 31.7 per cent. Chronic constipation and megalocolon in adults: excellent, 50 and 66 per cent; good, 50 and 33 per cent. Raynaud's disease: excellent, 71 per cent; good, 28 per cent. Buerger's disease: excellent, 66 per cent; poor, 33 per cent.

Transmission of Yellow Fever.—Hindle's studies showed that the incubation period of the virus in the mosquito may be as short as nine days at 28 C., or indefinitely prolonged at low temperatures. *Aedes aegypti* is capable of becoming infected if kept at a temperature not exceeding 18 C. An infected mosquito retains the infection for at least six weeks if kept at temperatures from 10 to 15 C. Mosquitoes that have ingested virus, if kept at from 10 to 15 C., fail to become infective, but if the temperature is subsequently raised to 28 C. they become infective. In one experiment, out of eleven mosquitoes that fed once on an infected monkey and were kept at 28 C. five (or six) failed to become infective, while five (or six) became infective. In some individuals the virus disappears from the body; in others the virus persists in the body but the bite does not become infective. A fatal infection was produced by the bite of one infected mosquito 118 days after it had become infected, and there seems no doubt that, once infected, a mosquito generally remains infective for the duration of its life. The inoculation of eggs laid by infected parents, and also larvae, pupae, and adults developed from such eggs, gave uniformly negative results. Males kept with infected females were found to become contaminated by the infected feces of the latter. Such contamination was merely on the surface of the males and was removable by washing. An infected mosquito remains infective after having fed on immune blood. In other words, the immune bodies have no action on the virus once it has become established in the mosquito. Mosquitoes that ingest immune bodies at the same time as virus fail to become infective. The prevention of infection seems to depend entirely on the strength of the immune bodies in the blood and is independent of the ingested dose of virus. As a result, the blood of a yellow fever patient ceases to be infective to mosquitoes long before the virus disappears from the blood. The blood of human yellow fever patients is highly infectious in the early stages and capable of spreading the disease by percutaneous infection, since the virus is able to pass through the intact skin.

Treatment and Diagnosis of Abscesses of Lung.—Pinchin and Morlock lay stress on the importance of a careful history, physical examination and pathologic investigation in the diagnosis of lung abscess. Radiology is of the most use, not in diagnosis but in location, in classification and in following the result of treatment. An acute lung abscess should, for a period of from six to ten weeks, be medically treated with postural drainage, during which time emetine, neoarsphenamine or other drugs may be employed. If, after this period, the condition is not clearing, surgery must be resorted to. If the case when first seen is judged from the history to be of longer standing than from six to ten weeks, it should be considered as chronic, and surgical treatment proceeded with. Artificial pneumothorax can be regarded as safe only in the deep-seated encapsulated abscess; its use in other cases must be carefully considered in regard to the comparative risks. The operation of choice is direct drainage performed in two stages under local anesthesia.

Unique Surgical Record.—Clements relates the case of a woman, aged 43 years, whom he saw in June, 1922. She gave a history of stomach trouble with vomiting of bile and always accompanied by severe frontal headaches; during the previous four months she had uterine hemorrhage. She had a cholecystotomy performed in 1916, when a large single stone was removed and the gallbladder drained. She felt much better after the operation until 1918, when she had a return of gastric pain. This was diagnosed as a duodenal ulcer for which a posterior gastro-enterostomy was performed. No benefit resulted from this operation. In 1922 Clements found her markedly tender over the gallbladder and pyloric region, and on vaginal examination she was found to have a typical malignant cervix. Clements performed a hysterectomy (Wertheim). She unfortunately developed a vesicovaginal fistula, which was repaired in August, 1922. In April, 1923, Clements performed an appendicectomy for an acute attack. In January, 1924, she showed signs of bladder trouble, suffering from frequency of micturition, accompanied by severe pain; this was due to calculi, and she was operated on in January and November of that year. For two years she was free from any bladder symptoms, although the gastric symptoms still persisted. In January, 1927, her bladder symptoms returned in a more aggravated form, and it was found that she had a small sac connected with the base of the bladder. She was operated on for this in June, 1927; since that date she has shown no further bladder trouble. During all these years she was never free from abdominal pain, vomiting, headaches, and a feeling of fulness in the upper part of the abdomen. Clements saw her again in June, 1930, and found her in a typical attack of biliary colic. He performed a cholecystectomy, removing the gallbladder with twenty stones, and undid the gastro-enterostomy. She made an uneventful recovery. Today she is perfectly well and for the first time in twenty-eight years is free from any symptoms.

*Treatment of Simple Ganglion by Injections. P. McEvedy.—p. 902
Paraplegia in Hodgkin's Disease: Case. F. J. Poynton and K. E. Harris.—p. 903.

Action of Serum of Normal Individuals on Virus of Poliomyelitis.—Some time after the attack had occurred in the school (about six months), Fairbrother and Brown examined samples of serum from various pupils—convalescent and abortive cases, close and remote contacts. They found that immunity to the poliomyelitis virus, as indicated by the presence of antiviral bodies in the serum, is frequently present in normal people who have been in contact with definite cases of the disease without developing it. The results recorded here support Aycock's view that the observed immunity of adults to poliomyelitis is most probably due to "subclinical" infections.

Lymphangioma of Abdomen.—The case reported by Hill provides evidence that this condition results from a congenital malformation of the lymphatics. All stages are present, from completely formed lymphatics and cysts containing plain muscle-fibers in their walls to actively growing endothelial rods opening out later into channels and nodes consisting of basic reticular structure which are possibly incompletely formed lymph glands. Ducts running from the neoplasm toward the celiac region may be an attempt on the part of the tumor to coordinate itself with the normal lymphatic system.

Achlorhydria and Anemia in Advancing Years.—A hundred persons over 60 years of age and in normal health were selected by Davies and James and their response to the ordinary fractional gastric analysis recorded. None of the patients had suffered from digestive ill health. Arterial sclerosis was found in all to a varying degree, and the systolic blood pressure ranged between 120 and 250 mm. of mercury, with no apparent relation to the gastric secretion. The blood was examined in all cases showing achlorhydria, and the results were compared as a series with those of the group showing an abundant secretion of free hydrochloric acid. The condition of the tongue was also noted, whether rough and papillated, or smooth and glazed. Achlorhydria was present in 32 per cent; low secretion of hydrochloric acid in 12 per cent; normal secretion of acid in 43 per cent, and high secretion of acid in 13 per cent. A slight degree of anemia was found more frequently in cases showing a true achlorhydria than in those showing a normal acid secretion. Anemia was more common in cases showing a diminished pepsin secretion than in those showing a good secretion of pepsin. Atrophic changes in the mucous membrane of the tongue were more frequently associated with achlorhydria than with a normal secretion.

Treatment of Simple Ganglion by Injections.—McEvedy has treated many ganglions by injections of sodium morrhuate, and the results have been extremely satisfactory. The skin over the ganglion is carefully sterilized. A small quantity of local anesthetic is injected into the skin at the side of the ganglion with a fine needle. A needle of moderate bore is inserted at this point, and the contents of the ganglion are aspirated. With the needle still in the ganglion, 5 per cent sodium morrhuate is injected. The quantity will vary with the size of the ganglion, from 0.5 to 2 cc. After the injection the ganglion swells and may reach its former size and tenseness. There is mild pain for a day or two. If the quantity of sodium morrhuate is correctly judged, the ganglion reaches only about half its original size, the pain is slight, and there is no redness. After a few days the ganglion diminishes in size and quickly disappears. If the ganglion is still present at the end of two weeks it is again aspirated and injected, the quantity of sodium morrhuate being increased. If it is thought that the ganglion communicates with a joint, the patient is instructed to keep the limb at rest for a few hours following the injection. No joint pains have followed the injections, and there have been no complications.

*Olive Oil in Diet of Acetonemic Children. C. Sainz de los Terreros.—p. 609.
Some Errors of Diagnosis. N. Z. Oumikoff.—p. 612.

Congenital Stenosis of Duodenum as Anatomic Basis of Cyclic Vomiting.—Camera reports a case of cyclic vomiting with acetonuria that he observed for several years. From the first he was impressed by the resemblance of the entire syndrome to the symptoms of subvaterian stenosis of the duodenum. Roentgen examination confirmed the suspicion of a duodenal stenosis and the child was finally cured by an anastomosis between the first portion of the small intestine and the second portion of the duodenum, passing through the transverse mesocolon. The pathogenesis of so-called cyclic vomiting is as yet undetermined. The theories of acetonuria, appendicitis and hepatic disturbances have all been proved unreliable. Camera is convinced, however, that the character and syndrome of the gastroduodenal vomiting that is the chief feature of the disease may be explained if one considers a subvaterian duodenal stenosis as its anatomic basis. The stenoses, whether total or partial, are caused by a lack of or delay in the attachment of the mesocolon in which the entire large intestine has a tendency to fall into the small pelvis, and the mesenteric pedicle, because of this abnormal weight, compresses the duodenum against the posterior wall of the abdomen. Passage through the duodenum is thus blocked and habitual constipation, migraine, and sometimes hepatic intoxication result. The condition is also marked by periodic attacks of vomiting that correspond to those usually described as cyclic vomiting with acetonuria. When the attachment of the mesocolon is merely retarded, as is common in early childhood, the attacks are of short duration. The high localization of the stenosis explains the persistence of the vomiting, the absolute intolerance of ingestion of any substance, and consequently the rapid dehydration that results. Because of this localization of the stenosis, moreover, when the small free portion of the gastro-enteral tube is relieved of its alimentary content the vomit can consist only of the secretions of the gastric and duodenal glands. This liquid mass, driven back toward the stomach when it reaches the point of stenosis, is emitted as by regurgitation when the pylorus is open or with painful contractions when the pylorus is closed. These are the two types of vomiting observed in cases of cyclic vomiting with acetonuria. The acetonuria itself as well as other concomitant toxic conditions that are often present is the result of the mixing of the glandular secretions.

Blood Pressure in Normal Child.—Chabrun and Petrovitch measured the blood pressure of 450 normal children aged from 4 to 15 years. The Pachon apparatus was found to be much more accurate and easier to use than the Vaquez-Laubry method. They observed that the maximum, minimum and differential pressures gradually increased with age. The increase was especially marked between the ages of 12 and 14 years.

Olive Oil in Diet of Acetonemic Children.—Since infantile acetonemia is always caused either wholly or in part by a hepatopancreatic insufficiency due to a defective utilization of fats, Sainz de los Terreros advocates substituting olive oil so far as possible for all other fatty substances in the diet. He suggests giving children bread fried in oil, or dipped in sardine oil, as well as doses of pure olive oil. He also advises the use of cod liver oil in winter. This treatment, together with certain hepatic and pancreatic opotherapeutic preparations, produces an augmentation of the alkali reserve, a decrease in the attacks of acetonemia and a better utilization of proteins and carbohydrates, as well as an increase in the weight of the child. The author feels, moreover, that if olive oil were thus administered whenever hepatopancreatic insufficiency was suspected, most cases of acetonemia could be entirely avoided.

Acute Alcoholic Poisoning in Adults and Children: Coefficient of Fatal Alcoholic Imbibition. C. Simonin.—p. 624.

Action of Sodium Fluoride on Basal Metabolism of Rat.—Since sodium fluoride is known to produce hypertrophy of the thyroid in white rats, Goldemberg performed a series of experiments on rats to determine the influence of this compound on their basal metabolism. He used white rats, black rats and spotted rats (the product of crossing white with black rats). Sodium fluoride was given orally and by intraperitoneal injections. Taken by mouth, a daily dose of 3 or 4 mg. has a certain tendency to lower the basal metabolism; however, to obtain definite results it would be necessary to continue the doses for from six to eight months. From 28 to 35 mg. of sodium fluoride for each kilogram of weight, in aqueous solution of 1 per cent, injected intraperitoneally, is the minimum fatal dose for rats. A single dose of from 15 to 18 mg. for each kilogram of weight, in aqueous solution of 1 per cent, injected intraperitoneally, always produces a decrease in the basal metabolism of the rat. The decrease varies from 12 per cent to 63 per cent in different animals. It begins to appear fifteen minutes after the injection, becomes more intense, and may persist for several hours or even several days. A single dose of from 2 to 3 mg. for each kilogram of weight, in aqueous solution of 1 per cent, injected intraperitoneally produces different effects on the basal metabolism in different animals, and sometimes even varies in the same animal from day to day. The decrease in the basal metabolism thus produced can vary from 24 per cent in some cases to 28 per cent in others. The effects of the injection soon disappear and the basal metabolism returns to normal.

Chlorination and Alkalization of Organism in Acute Diseases: Tests of Chlorination and Alkalization.—Achard and Enachesco made a series of tests to determine the reciprocal action of chlorination and alkalization in acute diseases. As a test of chlorination they administered orally from 10 to 15 Gm. of sodium chloride, sometimes repeating the dose two days later. The chlorine in the blood serum, the chlorine in the urine, the alkali reserve of the blood, the p_H of the urine and the carbonates of the same urine were measured before the test and at regular intervals after the test. In patients without retention of chlorine the test was followed by a rapid elimination of chlorine in the urine; the alkali reserve and carbonaturia were lowered temporarily and then rose sharply. In patients in whom retention of chlorine existed, the same test did not cause increased elimination of chlorine, nor was there an immediate change in the acid-base equilibrium. A similar test was then made for alkalization by ingestion of from 10 to 15 Gm. of sodium bicarbonate. In patients without retention of chlorine the alkali reserve was raised, complete alkalinuria was produced, and the carbonaturia was greatly increased; at the same time chloruria was produced without modification of the chlorine content of the blood. On the other hand, when there was no retention of chlorine, the authors observed an increase in the alkali reserve, alkalinuria and carbonaturia, although chloruria was not produced. A combined test of both chlorination and alkalization gave the same results. The authors feel justified, therefore, in concluding that in a normal condition chlorination produces alkalinuria and alkalization produces dechlorination. However, when a pathologic retention of chlorine is involved, the organism may be chlorinized without being disalkalized, and it may be alkalized without being dechlorinized.

Treatment of Cerebrospinal Meningitis. P. Teissier and J. A. Chavany.—p. 1321.
*Colibacillurias of Digestive Origin: Treatment by Local Antivirus Therapy. R. Jahiel and J. Petetin.—p. 1326.

Colibacillurias of Digestive Origin: Treatment by Local Antivirus Therapy.—Jahiel and Petetin have secured excellent results with local autovaccination in a number of cases of colibacilluria in which other methods of treatment had proved inefficacious. The method employed is as follows: The colon bacillus is obtained from the urine of the patient. In the "vaccination of the intestine" the authors used a microbial emulsion made with a forty-eight hour culture on gelose in Roux boxes; the culture, emulsified in 100 cc., is placed in ten ampules. Since the most obvious symptoms of colibacilluric complications are usually observed in the bladder, vaccination of the bladder is the second part of the treatment, using filtrates of cultures in bouillon ten days old. The treatment of the intestine is undertaken first by administering to the patient morning and evening one ampule of 10 cc. of microbial emulsion, the injection preceded each time by a pill of bile to clean the mucosa and give the vaccine a better contact with the intestinal wall. The vaccine is administered while the patient is fasting. During the treatment the diet is so modified as to reduce the quantity of albumins. After about ten days the treatment of the bladder is initiated. The vaccine is instilled into the bladder in doses of from 10 to 20 cc. three times a week, or more frequently if it is well tolerated. A preliminary lavage of the bladder with sterile water should always be made to remove any mucus or pus that is present. The combined treatment of the intestinal tract and bladder should be continued for fifteen days. It may then be resumed after a week if necessary. Although the vaccination does not always completely eliminate the presence of colon bacilli in the urine, it does render the bacilli harmless by producing local immunization of the cells and thus suppressing pathologic manifestations of the presence of the bacilli.

Schweizerische medizinische Wochenschrift, Basel

60: 837-860 (Sept. 6) 1930

Cancer of Skin: Observations on Patients in Clinics at Bern. Naegeli.—p. 837.
*Incorrect Diagnosis of Appendicitis and Renal Disturbances Located on Right Side. H. Walthard.—p. 842.
*Occurrence of Tubercle Bacilli in Swiss Cheese. G. Sobernheim and H. Meyer.—p. 848.
Color of Urine. W. Graubner.—p. 851.
Hereditary Symmetrical Polydactylism. R. Nicole.—p. 853.

Incorrect Diagnosis of Appendicitis and Renal Disturbances.—Walthard cites several authors who have observed that the diagnosis appendicitis is frequently made incorrectly. He himself admits that about one fifth of the appendectomies performed by him were a failure because the symptoms on which the diagnosis appendicitis had been based were due to renal disorders on the right side. Symptoms from disturbances in the urinary system are most frequently mistaken for signs of appendicitis. The author shows how symptoms caused by such conditions as renal and urinary calculi, bladder disorders, inflammatory diseases of the renal pelvis, infections of the urinary passages, some forms of nephritis, tumors of the kidneys and a diseased prostate may simulate appendicitis and how they may be differentiated. He especially warns against a blind belief in the diagnostic value of tenderness at McBurney's point.

Occurrence of Tubercle Bacilli in Swiss Cheese.—Sobernheim and Meyer made bacteriologic examinations of 111 samples of Swiss cheese. Tubercle bacilli were not detected in the guinea-pigs or in the cultures. They also relate that in 1900, at the bacteriologic institute in Bern, cheese was made from milk into which cultures of tubercle bacilli had been introduced. In this experiment it was found that the bacilli were present only a comparatively short time. They died during the storage. They were not found later than the fortieth day despite the fact that the milk had been contaminated with an unusually large number of bacilli. The authors point out that Swiss cheese is usually not brought to market until it is from three to four months old.

Archivio di Ostetricia e Ginecologia, Naples

17: 547-594 (Sept.) 1930

Tuberculous Ovarian Cysts: Case. A. Albanese.—p. 547.
*Pernicious Anemia in Pregnancy. A. Volpe.—p. 560.
*Reproductive Function Under Influence of Overdoses of Ergosterol. G. Centanni.—p. 586.

Pernicious Anemia in Pregnancy.—Volpe studied hematicologically and clinically a number of cases of anemia in pregnant malarial patients, endeavoring to differentiate between pernicious anemia and other anemic syndromes in pregnancy. He reached the conclusion that pernicious anemia is a peculiar individual reaction to the toxic agent, and refuses to accept the etiologic importance of malaria.

Reproductive Function Under Influence of Overdoses of Ergosterol.—Centanni's study on ergosterol administered for the purpose of determining its influence on pregnancy revealed that that function is one of the most susceptible to the action of ergosterol; in fact, ergosterol may constitute a grave insult. However, if the dose of the substance administered is within therapeutic limits the pregnancy proceeds regularly, with the advantage that the child is born better developed and possessing greater vitality. On the other hand, if the dose is excessive, but the mother is able to survive, the insult is expressed in one of two ways, either conception is inhibited or the fetus dies and is either absorbed within the uterus or expelled through abortion. There remains, in any event, the great advantage of the substance when administered within therapeutic limits. The author is not prepared to say whether the effects of the excessive dose on the procreative function are referable to hypervitaminization or to a product that develops in association with the vitaminic principle.

Archivio di Patologia e Clinica Medica, Bologna

9: 499-604 (Aug.) 1930. Partial Index

*Arteriosclerosis of Pulmonary Artery. F. Schiassi.—p. 449.
*Thrombotic Infarction Caused by Primary Arteriosclerosis of Pulmonary Artery. G. Invernizzi.—p. 590.

Arteriosclerosis of Pulmonary Artery.—Schiassi describes a case of chronic cyanosis caused by arteriosclerosis of the branches of the pulmonary artery. For more than eight years the patient, aged 45, had intense cyanosis, which was even more intense when he made some effort. No other symptom of disease of the heart or of the respiratory tract appeared during that time. The patient (except for the dark color of his lips and of his complexion), appeared to be strong and healthy. He was able to continue at work (first as a peasant and later as a soldier serving at the front during the war). Only three weeks before death he presented a grave syndrome with disturbances of the heart and of the respiratory tract. The following observations were made at necropsy: There was arteriosclerosis obliterans of the right and left branches of the pulmonary artery, starting from the hilus pulmonis and extending to even the smallest branches of the artery. The trunk of the artery was dilated, but neither it nor the point of bifurcation of its two branches was affected by the sclerotic process. In both pleural cavities, large and strong adhesions were found. The author believes that the presence of cyanosis should suggest the diagnosis of arteriosclerosis of the pulmonary artery during life.

Thrombotic Infarction Caused by Primary Arteriosclerosis of Pulmonary Artery.—Invernizzi reviews the literature on the pathology of the pulmonary artery. He describes the clinical and anatomic observations in a case in which the patient, aged 53, while apparently in good health, presented a clinical picture of slow evolution constituted by hemoptysis, which at first was slight and became more and more intense. The patient died two months after the onset of the disease with a syndrome of anemia and cardiac insufficiency. At the necropsy, a thrombotic infarction of the right branch of the pulmonary artery was found. The thrombosis was caused by a generalized primary arteriosclerosis of the artery.

61: 333-418 (July-Aug.) 1930

*Weil's Disease in Italy. C. Vallardi.—p. 333.
Lipolytic Action of Saliva. O. da Rin.—p. 340.
Anatomic Researches on Spine in Indirect Colitic Syndromes: Visceral Pain. G. Invernizzi.—p. 354.

Weil's Disease in Italy.—Vallardi observed in October, 1929, almost simultaneously, two cases of spirochetosis in the region below Milan. The first patient died with grave icterohemorrhagic manifestations a few hours after admission to the hospital. The second patient recovered without treatment in about one month. The author calls attention to the preicteric symptomatology and to the possibility of suspecting an infection in the beginning. Both patients presented at the start a pseudomembranous angina. Of interest is the behavior of the Wassermann, the Meinicke and the Kahn reactions in the second case with absence of syphilis. The Wassermann reaction became intensely positive during the icteric period and then returned to negative with recovery. The Meinicke reaction was positive only twice, while the Kahn reaction was twice doubtful.

Giornale di Clinica Medica, Parma

11: 847-916 (Aug. 31) 1930

*Intravenous Calcium Therapy in Tuberculosis. G. Reggiani.—p. 847.
Intestinal Syphilis. S. Pilloni.—p. 865.

Intravenous Calcium Therapy in Tuberculosis.—Reggiani gives the first results of a systematic research to determine the exact morphologic reactions of the blood after intravenous injection of a calcium salt and in the course of treatment of tuberculosis. Examination of the blood from twenty minutes to half an hour after the first injection showed a decrease in the number of neutrophils, a corresponding increase in the mononuclear elements and a rather frequent state of eosinophilia, all of which reactions were transitory in character. While the increased number of eosinophils has been noted by various authors, the modifications in the leukocytic formula observed in these experiments have been previously reported only by Becker.

Treatment of Fractures of Long Bones.—Birt pleads for more simple methods of treatment of these fractures. He reports cases to illustrate the effectiveness of suspension, extension and the application of an adhesive plaster dressing as originally proposed by Bardenheuer. He enumerates the many advantages of this treatment: The cost is low; it is easy of application; it simplifies the transport of the patient; it favors callus formation; bloody effusions are absorbed early; it quickly allays inflammation; the apparatus is simple and active as well as passive motion can easily be instituted by the patient himself.

Postoperative Elevation of Diaphragm.—Nine cases in which a laparotomy was performed and in which symptoms developed soon afterward indicating a postoperative pulmonary development are reported by Breuer. In each case the roentgen examination disclosed an elevation of the diaphragm on the affected side. The symptoms consisted, in the main, of cough, and of pain on breathing and on pressure over the ribs overlying the insertion of the leaf of the diaphragm. In a few cases pain in the shoulder was also present. These patients all recovered but the diaphragm did not resume its original position. These symptoms developed without previous warning from the third to the seventeenth day after operation. The author believes that disease of the diaphragm and reflex disturbances must be considered in endeavoring to find a cause for the condition and that it has some relationship with the development of postoperative pulmonary complications.

End-Results of Reimplantation of Ureter into Bladder.—Dannheisser relates eight such cases. Two patients died shortly after operation, and in two others a nephrectomy had to be performed later. Of the remaining seven, six were examined from one and a half to ten years after operation. Five had a perfectly formed new ureteral opening, with good function of the kidney to which that ureter belonged; in three cases a hydronephrosis had developed but function was good. The author feels that his results warrant regarding this operation a conservative measure in these cases because it conserves kidney function in an organ which ordinarily is sacrificed. The reasons for implantation in the cases cited were: bladder tumors, including sarcoma and carcinoma; stones in the ureter; lesions of the kidney.

Treatment of Hemorrhage into Peritoneal Cavity.—The results of experiments on dogs are reported by Garibdzanjan and Ożereljeff. These dogs were bled slowly from the femoral artery so as to give opportunity to adjust themselves to the loss of blood amounting to 4.5 per cent of the body weight. In ten dogs the blood withdrawn was transfused into the peritoneal cavity; in ten it was transfused into a vein; in ten an equivalent quantity of physiologic solution of sodium chloride was transfused into a vein, and in three cases only the withdrawal of the blood constituted the experiment. The blood withdrawn and reinjected was first citrated, 0.02 per cent of sodium citrate per kilogram of body weight being added. Not one dog succumbed on the operating table; therefore it was assumed that the quantity of blood withdrawn was not inimical to life. Of the dogs receiving the blood in the peritoneal cavity, 50 per cent remained alive; 90 per cent of those transfused into a vein remained alive and 80 per cent of those receiving physiologic solution of sodium chloride remained alive. Of the latter group of dogs, and including the three that were merely bled, only one animal was alive after the sixth day. The authors conclude that the dangers of severe intraperitoneal hemorrhages are the disturbance of the cardiovascular apparatus, and anoxemia caused by the loss of many erythrocytes. The best treatment is allowing the blood to remain in the peritoneal cavity and adding physiologic solution of sodium chloride. They check the hemorrhage and remove enough of the blood to reinfuse (intravenously) from 400 to 500 cc. diluted with the salt solution in the ratio of 1:3. The remaining blood is left in the peritoneal cavity. This blood is rapidly absorbed, in one or two days, and has the advantage of resembling in characteristics the patient's own circulating fluid.

Incidence of Thrombosis and Embolism in Leipzig.—Sarafoff states that the experiences in the Leipzig clinic were similar to those of other clinics—a peak in the incidence curve in 1924 and another peak in 1929. More cases occur in cold weather than at other times of the year. Neither operation nor sepsis seemed to have any effect on incidence. The same was true with regard to the previous condition of the patient; the anesthesia, the roentgen examination and intravenous therapy all were without noticeable effect on the incidence. Women were affected three times as often as men; increasing age likewise showed an increase in incidence. The cases of pulmonary embolism occurred only among urban residents.

Primary Resection for Perforated Gastric and Duodenal Ulcers.—Judin analyzes two series, totaling 207 cases. In the first series, in which the patients were operated on during a period of three years and nine months, the ulcers were, in the main, sutured and a gastro-enterostomy was performed. The total mortality in this group was 24.4 per cent. If three cancer patients are excluded, the mortality was 22.5 per cent. The end-result is known in forty-eight cases. Half of these complain of various disturbances so that it may be said that this method of treatment is not satisfactory. The second series consisted of seventy-six patients operated on during the past year. In fifty-one, the stomach and duodenum were resected. The total mortality for the series was 22.3 per cent; the mortality in the resected cases was 11.9 per cent. Excluding three deaths due to other causes, the mortality in the resected group was 6.2 per cent. The author concludes, therefore, that early operation (performed in 67 per cent of his cases), consisting of resection of the stomach, should be considered, provided the age and general state of the patient are not contraindications. All operations should be performed under splanchnic anesthesia, and only at the beginning of the operation may ether be used.

Relation Between Cardiac Weakness and Angina Pectoris.—Kohn directs attention to the diverse opinion regarding the pathogenesis of angina pectoris. Some authorities assume a causal relation between cardiac weakness and angina pectoris, while others think that a spasm of the coronary arteries is the etiologic factor. The question whether cardiac weakness or the opposite, namely, overactivity of the heart, predisposes to angina pectoris is answered by the author in the negative; however, cardiac weakness may become manifest during and after an attack of angina pectoris. On the basis of his observations he is inclined to believe that a spasm of the coronary arteries is the etiologic factor in angina pectoris. For the therapy this is of significance so far as the theory, which considers cardiac weakness as the etiologic factor, has led to the use of cardiac stimulants. However, when it is considered that coronary spasm is the real cause, it becomes understandable that such stimulants as digitalis and strophanthin are more harmful then helpful, because they cause a stenosis of the coronary arteries and thus aggravate the condition rather than improve it. Instead of these stimulants, nitrites should be administered because they have an antispasmodic effect. If, as a result of their habit-forming properties, the effectiveness of the nitrites is reduced, papaverine or theophylline may be given with or without sugar solution. Atropine likewise has an antispastic effect. In cases of total occlusion of the coronary vessels, caffeine and camphor can be resorted to. After an attack of angina pectoris as the result of a total occlusion, rest in bed is necessary and the existing cardiac weakness may be treated with digitalis. In order to counteract the recurrent pain that results from medication with digitalis, an antispasmodic should be administered simultaneously with the digitalis.

Vaccination Against Tuberculosis, and Acquired Immunity.—On the basis of epidemiologic and statistical studies, Wolff reaches the conclusion that the decrease in the tuberculosis mortality is due neither to naturally acquired immunity nor to the vaccination methods of Friedmann or Calmette.

Oxygen Consumption Following Bodily Exertion.—Jahn points out that other authors, especially Hill, have come to the conclusion that the increased oxygen consumption during and after bodily exertion is due to the oxidation of the lactic acid that forms in the muscles. However, recent investigations have proved that in the provision of the tissues with oxygen many factors are involved. The author made several experiments. First he gave intravenous injections of a solution of lactic acid to healthy persons and to patients. He found that the oxygen consumption following intravenous injection of lactic acid is much in excess of the oxidative value of the injected substance, and he therefore assumes an irritative action of the lactic acid. This proves that there is no quantitative relation between the increased oxygen consumption and the lactic acid. Later, exertion experiments were made on thirty-five persons. It was noted that following completion of the work the basal metabolism was reduced and only after two hours was it normal again. Diagrams of the results of several other tests are given and the author comes to the conclusion that the lactic acid has an irritating effect on the system regulating the metabolism. However, this action is exerted only by that portion of the lactic acid that goes into the blood stream. Hill's theory regarding the quantitative relation between lactic acid formation and oxygen consumption is therefore no longer tenable. The irritative action probably involves many factors and is dependent on the condition of the sympathetic nervous system. The changes in the basal metabolism following work tolerance tests frequently indicate the individual reaction of a person.

Significance of Raw Egg Yolk for Glycogen Deposition in Liver.—Abelin points out that although egg yolk is not a carbohydrate it nevertheless exerts a great influence on the sugar metabolism. Experiments on rats proved that egg yolk increases the capacity of the liver to form glycogen The same quantity of cane sugar produced larger quantities of liver glycogen in animals that had received egg yolk than in animals that had not been given egg yolk, although their diets had otherwise been the same. In some instances the glycogen content of the muscles was likewise increased. These manifestations may be given various interpretations. In the first place, one would think of the most important factor of glycogen formation; namely, of insulin. On the other hand, the high vitamin content of the egg yolk may be of a certain significance. According to recent investigations the liver stores large amounts of vitamins, especially vitamins A and B. It may be assumed that the vitamins participate in the intensive metabolic processes within the liver. The egg yolk provides large quantities of vitamins A, B and D. But whatever the mechanism of the action of the egg yolk, its glycogen increasing action is of significance for the therapy. Without doubt, besides diabetes mellitus there are other disturbances that impair the glycogen metabolism of the liver, and whenever glycogen deficiency exists the therapy should utilize egg yolks.

Influence of Administration of Bilirubin on Blood.—In investigations on the action of several substances on the formation of blood, bilirubin was likewise tested. The experiments that Popper reports were made on human beings. When 0.05 Gm. of bilirubin was injected intravenously, it was found that the hemoglobin content increased temporarily; however, the number of erythrocytes remained unchanged. The experiments did not reveal whether the increase in hemoglobin was due to a stimulation of the hemoglobin forming organs or to an arrest in the disintegration of the hemoglobin.

Diathermy in Myelitis.—Because other authors had observed that poliomyelitis and other chronic cerebral and spinal diseases could be influenced by diathermy, Österreicher attempted diathermy treatment of the spinal cord in a case of sporadic myelitis. He employed a strip electrode that covered the cervical, the thoracic and the upper lumbar vertebrae. A large plate electrode was placed on the abdomen. The intensity of the current was 0.7 ampere, and the first treatment lasted ten minutes. The time was gradually increased to thirty minutes. The treatment was repeated three times a week. After the third diathermic heat application the patient already showed considerable improvement. After five months the recovery was nearly complete. This favorable result induced the author to institute diathermy treatment in two other patients with myelitis. In these cases he likewise observed a remission of the paralysis and of other neurologic symptoms, and the pathologic changes in the cerebrospinal fluid disappeared. Further investigation of this therapeutic method is recommended.

Influence of Diet, Deficient in Sodium Chloride, on Gastric Secretion.—Cohen describes his tests in three patients who, for longer periods, had received a diet deficient in sodium chloride; that is, they received daily only from 1 to 1.5 Gm. of salt. The secretory function of the stomach was determined by means of fractional withdrawal of the gastric juice following ingestion of tea. It was found that the salt-deficient diet had not caused a disturbance in the secretion of hydrochloric acid.

Streak Shaped Growth Inhibition of Hair in Patients with Angina Pectoris or Thrombosis.—The growth inhibition of the hair of the head that Neuda noted in patients with angina pectoris, or in those who show a predisposition to thrombosis, is located behind the ear and on the occiput. This manifestation should not be confused with psilosis, for it is only a retardation of the growth. In the discussion of the pathogenesis of this symptom, the mechanisms of thallium alopecia and of syphilitic psilosis are mentioned, and likewise the psilosis of the lateral portion of the eyebrows. Special emphasis is put on the connection with gastro-intestinal disorders. Still more significant, however, appear certain hereditary influences. Investigations on the heredity of patients who show this symptom revealed diseases with an intense toxic influence on the organism, such as cancer and syphilis, and it is probable that the after-effects of this toxic influence become manifest in the offspring.

Menopause: Changes in Blood Pressure.—Von Magyary states that in women during the menopause one can frequently demonstrate a disturbance in the regulation of the blood pressure. The disturbance may be present even in cases in which the level of the blood pressure is not increased. Treatment with ovarian preparations is frequently followed by a return of the blood pressure to normal. It is therefore evident that in the majority of cases the blood pressure disturbances during the menopause are caused not by pathologic changes in the kidneys or blood vessels but by the loss of function of the ovaries.

Vaginitis: Biologic Method of Treatment.—In the treatment of inflammations of the vagina, Andreitschuk uses a biologic method recommended by Smorodintzew and Tumanow; namely, the introduction into the vagina of pure cultures of *Bacillus vaginalis.* The technic used is as follows: A cotton tampon is saturated with a dextrose-liver broth and to it is added a few drops of a twenty-four or forty-eight hour culture of *B. vaginalis.* After a preliminary irrigation of the vagina with a physiologic solution the tampon is introduced and is left in place from twenty-four to thirty-six hours. To prepare the dextrose-liver broth, a beef liver is cut into large pieces and boiled for thirty minutes in double its amount of water with the addition of 1 per cent of peptone and 0.5 per cent of sodium chloride. The preparation is then filtered, to it is added 2 per cent of dextrose, and the resulting solution is rendered slightly alkaline or neutral. It is then boiled thirty minutes longer, filtered, and sterilized by exposure for forty-five minutes in a current of steam; the sterility of the broth is controlled by placing it for a time in an incubator. The author has used this form of treatment in thirty-five ambulatory patients whose chief complaints were a condition of vaginal irritation accompanied by a sensation of burning and pruritus. Most of them had been under other forms of treatment and stated that although the condition had been relieved temporarily it reappeared when the treatment was discontinued. Of the thirty-five patients given the biologic treatment described, two (6 per cent) did not show improvement, thirteen (37 per cent) improved, and twenty (57 per cent) recovered completely.

Malignant Tumor of Cervix in an Infant.—Kohlhaas reports a case of malignant tumor of the cervix in an infant aged 16 months. The first manifestations of the disease began when the infant was 6 months of age. At that time the mother noticed blood on the diaper and that the infant would no longer suckle. On examination it was found that blood was issuing in small quantities from the genitalia and this continued for three days. At the same time a malodorous discharge appeared and this persisted. The hemorrhage reappeared at intervals of three or four weeks and lasted several days. In spite of the loss of blood, the infant grew well and at the age of 12 months learned to walk. Shortly before and during the hemorrhage she felt unwell and did not eat or play. At the age of 14 months a profuse hemorrhage occurred and the patient was hospitalized. The hemorrhage was stopped by means of a hemostat and tamponade. Repeated examinations for gonococci were then made but none were found. The microscopic examination of detached pieces of tissue revealed a malignant epithelial tumor of the uterus. Under symptomatic treatment the condition progressed rapidly and the child became thin and anemic and died two months later. Postmortem examination disclosed a malignant tumor of the cervix and vagina with extension into the neighboring tissue and compression of the ureters and urethra. Above the point of compression of the urethra it was dilated, as was also the bladder, whose muscular layer was hypertrophied. The ureters, likewise, were dilated and the kidneys presented an extreme degree of hydronephrosis. The uterus was dilated and the myometrium was hypertrophied. Tumor metastases were found in the para-aortic lymph nodes, the liver, the right lung and the right bronchial lymph nodes. Tracheobronchitis was present and both lungs contained foci of bronchopneumonia. The primary tumor had perforated into the common iliac vein, which was thrombosed. Microscopic examination of the tumor of the cervix and of its metastases revealed the same histologic picture. The cells varied in size and most of them resembled epithelium and had large, lightly stained nuclei and a large amount of protoplasm. Some of them, however, were spindle-shaped and resembled fibroblasts. A few contained more than one nucleus and in a few the nucleus was club shaped. Mitotic figures were not numerous but there was a large amount of necrosis and inflammatory infiltration. Since the microscopic picture was not that of a pure carcinoma and still less that of a sarcoma, the condition was diagnosed as an immature malignant tumor.

Basal Metabolism in Diabetic Children.—In metabolism determinations (Knipping's method) in seven diabetic children, Beck noted that in the acute stage of the disease the basal metabolism was always definitely increased. Following the administration of insulin, however, it diminished. Each exacerbation of the diabetes was accompanied by an increase in the basal metabolism. In infections accompanied by fever, the basal metabolism was greatly increased; the increase appeared before the elevation of temperature began and lasted a long time after it had disappeared.

Diphtheria: Treatment with Convalescent Serum.—Because of the inefficacy of even large doses of diphtheria antitoxin administered early in the recent epidemic of diphtheria in Munich, Hentschel decided to use serum from convalescent children in from the first to the third week of the disease. Two children with a light form of the disease and five with severe pharyngeal diphtheria were treated exclusively with convalescent serum. In sharp contrast to control patients, all the patients treated with convalescent serum made a smooth recovery. It was noted, however, that in the patients treated with convalescent serum the membrane was cast off on an average one day later than in the control patients.

Glandular Fever: Epidemic.—Scheer describes an epidemic of glandular fever that occurred in a children's home and in which the disease was contracted by forty-three nurslings and small children and two nurses. In most of the cases the disease ran a typical course, beginning with a rapidly increasing fever that usually reached 40 C. (104 F.) and then fell by lysis after a few days. The enlargement of the cervical lymph nodes began in most cases one or two days after the appearance of the fever and involved chiefly the nodes in the region of the insertion of the sternocleidomastoid muscle. These lymph nodes enlarged to the size of a plum and had a peculiar tense elastic consistency. In five cases the course of the disease was severe. The fever persisted with remissions for a week and the characteristic thing about it was the appearance of periods of subnormal temperature, particularly at night. In one child a retropharyngeal abscess developed and underwent spontaneous evacuation. Eight days later the lymph nodes on the same side of the neck became necrotic and were incised. A large amount of pus was withdrawn which, like the pus from the retropharyngeal abscess, contained a weakly hemolytic streptococcus in pure culture. In another child also after the disease had persisted for four weeks and the fever had disappeared and the inflammation in the lymph nodes was retrogressing, a deep retropharyngeal abscess developed and was incised. Pus from the abscess was found to contain several kinds of bacteria with a predominance of diplostreptococci. All of the five patients in whom the course of the disease was particularly severe recovered.

Whooping Cough: Vaccine Treatment.—In the treatment of whooping cough, Kramsztyk uses Besredka's vaccine treatment with a bacterial filtrate of pertussis bacilli to which is added a filtrate of bouillon cultures of other bacteria found in the pharynx of children in various stages of whooping cough. At first the pharynx was painted with the filtrate, but this method was found to be unsatisfactory and the atomized method was adopted and the pharynx was sprayed with the filtrate three or four times daily. After from three to eight days of this treatment, both the number and the intensity of the paroxysms decreased. In patients in whom the treatment was begun early enough, the disease ran an abortive course and the convulsive stage did not appear.

Diphtheria: Insulin-Dextrose Treatment.—In the treatment of 141 patients with diphtheria, Kostyál obtained good results with the combined administration of insulin and dextrose. Of the basis of his experiences he recommends an extensive trial of the method, the object of which is to supply the glycogen-deficient liver with this substance and thus stimulate its metabolism and detoxication action.

Occurrence and Causes of Anemia in Renal Disturbances.—Becher asserts that the pale appearance of patients with renal disease is usually due to anemia and not to an angiospasm in the skin. The anemias in patients with renal disturbances are of the type of secondary anemias with low color index, and they may be slight or severe. Anemias of a minor degree, in which the hemoglobin content does not go below 70 per cent of the normal, develop in the absence of a renal insufficiency. These forms of anemia are caused either by hematuria or by the disease that led to the renal disturbance. In the second stage of the diffuse glomerular nephritis there develops likewise such anemias of minor severity. Probable causes of these anemias are a disturbance in the formation of blood or a limited blood supply of blood-forming organs. Other forms of anemia that occur during renal disturbances are those caused by hydremia. They develop either as the result of intravascular retention of water or when the water content of edematous tissues is brought into the blood. In anuria there develops a relative anemia as the result of increasing thinning of the blood. It is probable that in these cases the retention of urea forces the water from the tissues into the blood. Several forms of anemia with a hemoglobin content of about 50 per cent are always found during true renal insufficiency with isosthenuria, pale urine and retention of products of intestinal putrefaction in the blood and in the tissues. This more severe form of anemia develops simultaneously with the retention of the products of intestinal putrefaction and goes parallel with it. It is probable that the products of intestinal putrefaction produce this anemia. The anemia seems to be due to a diminished formation of blood, because signs of an increased disintegration do not exist.

Clinical Significance of Tubercle Bacillemia.—Löwenstein states that tubercle bacilli frequently enter the blood stream. However, there is no clinical symptom on the basis of which tubercle bacillemia can be diagnosed, and up to now there has been no reliable method by which the presence of tubercle bacilli in the blood stream could be demonstrated. First it is discussed as to how the tubercle bacilli enter the blood stream, and then how their presence may be detected. The microscopic demonstration has led to disappointments so frequently that it has been completely given up. The demonstration by animal experiment has the disadvantage that it requires too much time, and consequently the cultivation method has been further developed. The sulphuric acid method, which was perfected by the author several years ago, permits a pure culture of the tubercle bacillus, in that the 15 per cent solution of sulphuric acid destroys all other bacilli. However, cultivation from the blood involves several other difficulties. A suitable nutrient medium had to be found, and because hemoglobin and peptone hinder the cultivation of the tubercle bacillus, a nutrient medium was prepared that contained not peptone but asparagin as the nitrogen source. The medium is prepared from eggs, asparagin and congo red. The technic of cultivation is described. The second part of the article describes the results of the culture test in the various forms of tuberculosis. That tubercle bacilli may be present in the blood stream even when the patient does not have fever was demonstrated in cases of tuberculosis of the lungs, larynx, kidneys, skin, eyes and bones. In two cases of skin disease in which the diagnosis was difficult, the cultivation method revealed tubercle bacillemia. The cultivation method was also employed in twenty cases of erythema induratum and fourteen positive results were obtained. In nine cases of lupus erythematosus there were positive reactions in seven instances. Of four cases of papulonecrotic tuberculid, four gave a positive culture. Of eight patients with genuine tuberculosis of the skin, six gave a positive reaction. In twelve cases of lupus vulgaris the blood culture was positive in four instances. The author comes to the conclusion that his method, which permits a direct demonstration of the disease virus from the blood, is of greater clinical significance than the tuberculin reaction.

Diphtheria Prophylaxis by Means of Löwenstein's Ointment.—Siegl and Hassmann report their observations on forty children who were immunized against diphtheria by means of Löwenstein's ointment. The ointment, which is prepared from a detoxicated unfiltered culture, contains toxoid and killed bacilli. The inunctions are repeated three times at intervals of from ten to fourteen days, and 3 cc. of the ointment is applied each time. In order to test the efficacy of the inunction method the children were subjected to Schick tests. It was found that the immunity develops slowly. But after four months thirty-two of the forty children had become Schick negative. On account of the slow development of the immunity, the immunization should be done during periods when diphtheria is not prevalent. The vaccination with toxin antitoxin mixtures, with toxin antitoxin floccules or with diphtheria toxoid often cause painful local reactions and for that reason often meets opposition. Löwenstein's inunction method, however, is entirely painless and is not dangerous. Accordingly, the authors recommend its wider application.

Tonsillectomy During and Shortly After an Attack of Tonsillitis.—Levinger performed tonsillectomies on 235 patients with peritonsillar abscesses. In sixty of the patients the operation was immediately preceded by a tonsillitis. On the basis of his experiences he comes to the conclusion that the opinion now generally held, that tonsillectomy should not be done during or shortly after an attack of acute tonsillar diseases, is no longer tenable, because this expectant attitude does not always prevent complications. The author thinks that complications are usually caused by a too radical operation at the lower pole of the tonsil. That during his tonsillectomies complications did not develop in spite of the fact that acute inflammations existed, is considered to be the result of his procedure to avoid a complete removal at the lower pole. It is asserted that, provided all the deeper recesses are removed, a tonsillar stump may remain at the lower pole, because even a radical removal does not prevent the after growth of tonsillar tissue. The author stresses that tonsillectomy is not only permissible during the existence of a peritonsillar abscess but is the most favorable form of treatment, especially in cases of recurrent abscesses.

Burns: Prevention of Pain and Treatment.—Novak contradicts the theory advanced by the Sauerbruch clinic that *solutions of procaine hydrochloride-epinephrine create unnatural* conditions in the tissues and thus lower the resistance against infections. This is the case only if, as solvent for the procaine *hydrochloride, either a neutral or a weakly acid physiologic* solution of sodium chloride is employed, because such a solution would not be iso-alkaline with the blood. But if a solution is used that has the alkalinity of the blood the results are favorable. This has been corroborated by several investigators. The author advises that burns be treated by applying immediately sterile cotton compresses that have been saturated with the solutions designated. After from ten to twenty minutes, the compresses are changed. If the burns are deep, the compresses should be applied for about three hours. When this treatment is employed the pain ceases almost instantly, minor blisters disappear after a short time, and the skin becomes again attached to the tissue. The further treatment is done by dusting the wound with iodoform. Wounds that are kept aseptic heal without scars in from eight to ten days. As the main advantage of this treatment the author considers the fact that the pain ceases almost instantly, and this relief of the injured person effects an increase in the resistance and thus promotes the healing process.

Effect of Dry Diet on Growth of Inoculation Tumors.—Ottensooser states that a dry diet leads to a decrease in the body weight of mice not inoculated with cancer and of the gross weight of mice inoculated with cancer. The injury of the animals is accompanied by a retardation in the growth of the tumor. The length of life of the tumor mice is shortened by the dry diet, but the tumor, compared with the length of life or the net weight of the animal, is affected more by the nutritional injury than is the host. A decrease in the number of positive inoculations occurs only in a series in which the mice are placed on a dry diet before they are inoculated. Metastases are almost completely inhibited by a dry diet. The author believes that the effects of a dry diet on the transplantability, *growth and metastasis of inoculation tumors in mice* are produced entirely or almost entirely by the general quantitative undernutrition.

Blood Changes in Chickens with Rous Sarcoma.—Sadi reports the results of his examination of the blood of seventeen chickens with Rous sarcoma. In all the chickens there was an increase in the number of polymorphonuclears. Their proportion varied from 35 to 80 per cent. This corresponds with the increase in these cells that is usually observed in human beings with cancer. The number of polymorphonuclears did not seem to be directly dependent on the size and degree of ulceration of the tumor. In only two cases was there an increase in the number of eosinophils and in four cases none were present. In all the cases there was present a monocytosis ranging from 15 to 39 per cent. This corresponds with the slight monocytosis observed occasionally in human beings with cancer. The number of mast cells remained unchanged. In most of the cases there was a marked lymphopenia; in one case the proportion of lymphocytes sank to 3 per cent. Immature forms of leukocytes were observed rarely; in only three particularly severe cases were one myelocyte and one promyelocyte observed.

Esophagoplasty.—Pokotilo describes two methods of operating for stricture of the esophagus which make use of skin flaps to supply the excised part of the esophagus. One of these takes a quadrilateral flap from the skin of the neck: the other makes use of a tongue-shaped skin flap from the upper part of the chest wall. A complete description, with illustrations, of each procedure is given.

Hormone of Anterior Lobe of Hypophysis in Tissues from Cystic Mole or from Chorio-Epithelioma.—Zondek points out that in patients with cystic mole or with chorio-epithelioma the urine contains much larger quantities of the hormone of the anterior lobe of the hypophysis than during pregnancy. Examination of the wall of the cystic mole has revealed that its hormonal content is considerably greater; namely, about five times as great as that of the normal placenta. In a chorio-epithelioma the hormone exists likewise in large quantities. These observations suggest a new diagnostic method, namely, the examination of excised tissues, or those which have been removed by curettage, by means of the implantation method. However, on account of the toxicity of the tissues, especially in case of chorio-epithelioma, the animals often die. Before implantation the tissues should therefore be detoxicated by placing them for twenty-four hours in ether and then drying them by exposure to the air. The ether extracts the poisonous substances but not the hormone, and the animals do not die. In this manner it was possible to test even malignant tumors. By means of sarcomatous tissues from the testes of two patients, the typical hypophyseal hormone reaction could be produced in the animal experiment. This indicates that a correlation exists between malignant tumors of the male genitalia and the anterior lobe of the hypophysis. In cases in which chorio-epithelioma is suspected, tissues excised from the vagina or from the portio vaginalis are implanted into a test animal after previous detoxication. Whenever *this implantation results in the hypophyseal hormone* reaction, the diagnosis chorio-epithelioma is correct because normal tissues do not give a reaction.

Ovarian Dermoid Perforated into Sigmoid.—Mayer reports the case of a woman with dermoids of both ovaries in whom the right dermoid perforated into the sigmoid. Between the first and the second operation fifteen years elapsed, and during this time the patient was never free from pains. It appears that during the first operation the dermoid cyst on the right side had not been completely removed. In the course of the years it became again enlarged and finally perforated into the intestine. The patient discovered hair in the fecal discharge and after that asked medical advice. The examination and the operation are described. By means of cecal fistula the suture on the intestine was protected in the beginning, and the much weakened patient finally recovered.

Peculiarities of Glycemic Reaction in Early Infancy.—Styrikovich has studied the various phases of the glycemic reaction in infants and on the basis of his observations recognizes the following three types of the reaction: (1) type with curves showing a single rise, encountered in only 37 per cent of the cases, this form being less characteristic of infancy; he distinguishes three subtypes: (*a*) rise to a considerable height and a more or less rapid descent to normal; (*b*) rise to a moderate height, remaining at that height for a time (one hour or longer), sometimes a slight wavelike fluctuation, thereupon a drop—in some cases with a tardy hypoglycemia; (*c*) rise to a modest height with subsequent drop to a lower level on an empty stomach; (2) type with curves with two rises, which also may be divided into three subtypes: (*a*) second rise lower than the first; second wave of smaller volume than the first; (*b*) second rise attaining or surpassing the level of the first, and the second wave in volume equal to or exceeding the first; (*c*) second rise rapid and in a short time return to normal; (3) type with curves with three rises (a rare form).

Taccone Test for Differential Diagnosis of Tuberculous and Serous Meningitis.—Chistyakova states that his observations on the Taccone test have led him to the conclusion that that test is by far more sensitive than all other albumin tests and, more particularly, than the Pandy test. Secondly, he brings out that the Taccone test not only reveals an increased amount of albumin occurring in every inflammatory process but also affords an opportunity of discovering macroscopic manifestations of albumin formation in various types of disease of the central nervous system, and, more especially, makes possible a sharp differentiation between serous meningitis and tuberculous meningitis. Whereas a positive Pirquet reaction would indicate the presence of a tuberculous infection somewhere in the organism or, in certain cases, the existence of a primary serous meningitis, the Taccone test would, in the latter event, point to a nontuberculous serous meningitis.

Bacteriophage in Treatment of Patients with Typhoid.—The bacteriophage used by Ruchka and Melnik was prepared as follows: To each 100 cc. of a bouillon, 1 cc. of which contained 250 million typhoid bacilli, 2 cc. of bacteriophage was added. After a thorough stirring, the mixture was placed in an incubator at a temperature of 37 C. (98.6 F.) for from twelve to eighteen hours. Then it was passed through a Chamberland L^5 filter, left in the incubator for one or two days, and poured into sterile tubes or ampules. The latter were placed in the incubator for a few days. The bacteriophage was not used before having been kept for a few weeks at room temperature. Its titer was 10^8. The harmlessness of the bacteriophage was ascertained by subcutaneous or intravenous injections in rabbits. Moreover, 10 cc. of the bacteriophage was taken orally by one of the authors. Of sixty-nine patients with a severe form of typhoid, fifty-two were given the bacteriophage orally; seventeen were given subcutaneous injections. Usually one dose of 10 cc. of the bacteriophage was given in water, containing a small amount of sodium bicarbonate, on fasting; rarely the dose was repeated the next day. In cases of subcutaneous injections, a dose of from 1 to 3 cc. was given in the abdominal wall; in a few cases the injection was repeated. The reactions to the bacteriophage consisted in the development of diarrhea, in a reappearance of the rash and in increase in perspiration. The bacteriophage treatment almost constantly resulted in a decrease in the fever by 1 or 2 degrees, two or three days afterward; in most of the cases, this was preceded by a rise in the temperature by from 0.3 to 0.8 degree. The general condition improved the next day. The reactions were more pronounced when the bacteriophage was used subcutaneously. Of the patients treated, four (5.8 per cent) died. One of them contracted erysipelas after having recovered from the typhoid, another was admitted to the hospital in a hopeless condition and a third suffered with a grave pneumotyphoid. During the same epidemic, the mortality among patients not treated with the bacteriophage was from 7.5 to 8.5 per cent.

Organic and Inorganic Phosphorus Content of Blood in Children.—Fedorov examined 1,000 samples of blood withdrawn from 254 healthy children, aged from 7 to 15. The average amount of inorganic phosphorus in the blood of boys and of girls proved to be about the same; it was 3.97 mg. per hundred cubic centimeters. The amount of the organic phosphorus was 6.02 mg. per hundred cubic centimeters. According to other authors, the amount of inorganic phosphorus in the blood of young children varies from 4.2 mg. to 5.2 mg. per hundred cubic centimeters; in the blood of adults it varies from 2.4 mg. to 2.8 mg. and it reaches about 1.85 mg. at the age of 50. While the total amount of the inorganic and organic phosphorus was about 10 mg. in children, that in adults was found to be from 10 to 11 mg. While the total amount of the phosphorus is about the same in children and in adults, the ratio between the inorganic phosphorus and the organic phosphorus differs in them. The author assumes that there is a connection between the amount of the inorganic phosphorus and the intensity of oxidation processes in the organism. Thus the amount of the inorganic phosphorus decreases in adults because the oxidation processes are reduced; it is lowered also in children with rickets on account of a diminished metabolic rate. Fedorov did not observe any seasonal changes in the amount of the inorganic phosphorus, in children.

Troubles in Circulation of Skin in Rheumatic Diseases.—The observations in disturbances in the circulation of the skin in rheumatic sufferers, van Breemen states, are of full significance for the place of observation only and comparisons with countries that have another climate or a different type of population cannot be made without considering these differences.

Omarthritis Accompanied by Vasomotor Disturbances.—The ordinary isolated arthritis of the humeroscapular articulation, omarthritis, is a typical form of arthritis which, at least in Sweden, is of common occurrence. It generally occurs in presenile years, round about 60, and is characterized by an increasing stiffness usually in one of the shoulder joints. The patient notices that something prevents him from carrying his hand behind the neck (to the hair) or behind the back (e. g., in buttoning his braces). To start with this restricted movement in the shoulder joint is the only symptom. The stiffness increases, and the movements are executed with greater and greater difficulty and elicit gradually more pain. Spontaneous pains, aching, are as a rule altogether absent at first. Later on a fairly moderate spontaneous ache often sets in, typically distributed from the anterior aspect of the humeroscapular joint along the anterior medial border of the humerus down to the inner humeral condyle. The pain in the uncomplicated form of omarthritis does not extend any farther, unlike the pain of primary brachial neuralgia, which at the outset radiates right down to the wrist and often frequently right out to the tips of the fingers. In a case of long standing, for weeks or months, it sometimes gives rise to secondary neuralgia, which then of course naturally extends down to the fingers. Kahlmeter, however, has found such forms of neuralgia secondary to omarthritis unusual. The prognosis of the ordinary "presenile" omarthritis is exceedingly favorable if rightly treated; i. e., exclusive treatment by movements. The etiology is entirely obscure. In most of these cases of omarthritis with vasomotor trophic disturbances of the hands and fingers the patients are at the same time suffering from an exceedingly well marked anxiety neurosis. The course of procedure is usually that the patient begins to complain of discomforts in his shoulder simulating an ordinary omarthritis: he begins to feel difficulties in moving his shoulder. Fairly soon, however, and often before the stiffness in the shoulder has as yet become particularly well marked, the hand and fingers begin to swell and at the same time a condition of anxiety sets in. The patient becomes depressed and brooding, anxious and worrying about everything, weeps easily, and so on. In some cases the picture is one of a true melancholia with inhibition and ideas of sinfulness, but as a rule it is the anxiety and the tendency to weeping that remain the dominating features. As far as Kahlmeter has been able to ascertain, most of the patients have never before shown the slightest sign of neurotic tendency, at least of any marked degree. He is convinced that their anxiety in most cases is a temporary clinical symptom not based on reaction of an originally neurotic individual to the discomforts of a somatic disease but a symptom just of this somatic condition analogous with other so-called somatic symptoms. He is convinced that the omarthritis, the vasomotor disturbances in the hands and fingers and the anxiety have all a common cause, that they are collateral symptoms, and this is supported by the fact that in the recovery of the patient which, as a rule, is the case, the anxiety as well as the vasomotor changes undergo simultaneous and parallel improvement while the mobility in the shoulder joint returns.

Acta Chirurgica Scandinavica, Stockholm

66: 275-489 (Sept. 1) 1930

Right Osteogenic Genu Varum with Congenital Hemiatrophy of Upper Tibial Epiphysis. H. L. Rocher and G. Roudil.—p. 275.
*Case of Echinococcus Cysticus Intraspinalis. C. C. Fleischer-Hansen.—p. 293.

Studies in Wound Infections. F. Serck-Hanssen.—p. 372.

Case of Intraspinal Echinococcus Cyst.—The case of a married woman, aged 49 years, is recorded by Fleischer-Hansen, in whom both the neurologic and the roentgenologic examination revealed a tumor medullae spinalis at the level of the eighth dorsal segment. Through laminectomy, with removal of the arches of the sixth, seventh and eighth dorsal vertebrae, at the level of the seventh dorsal vertebra, an intraspinal, epidural cyst, almost the size of a plum, was revealed which proved to be an echinococcus cyst with the typical cyst wall, daughter cysts, hooks and scolices. The cyst was removed and the patient recovered.

Peculiar Case of Carotid Tumor.—Bager describes a case of tumor of the carotid gland atypically situated on the medial aspect of the carotid artery and quite distinct from this. On resection about a year later of the considerably enlarged left thyroid lobe, this was found to be made up of a tumor of identically the same carotid type. It was probably a question of metastasis at an early stage in the thyroid.

Acute Free Perforation of Gastric and Duodenal Ulcers.—Semb's analysis of 166 cases shows a considerable increase—absolute and relative—in the number of juxtapyloric ulcers in young men. The treatment adopted in the greater number of cases was suture and gastro-enterostomy with flushing out of the abdomen through a crisscross incision in the right fossa iliaca. This treatment has, especially in the juxtapyloric ulcers, yielded excellent results. Primary gastro-enterostomy is well endured. It does not seem to involve any great danger for the spreading of infection and it affords excellent drainage of the stomach. Postinvestigation shows that gastro-enterostomy in case of perforating ulcer yields a larger percentage of cures than is usual in cases of chronic ulcer.

Two Cases of Cardiospasm and Dilatation of Esophagus with Successful Operation by Heyrovsky's Method.—Häggström relates two cases of cardiospasm in which esophagogastrostomy brought about good results. The first case was that of a girl, aged 20, who at the age of 13 had been taken ill with diphtheria and who on the third day of illness developed difficulties in swallowing, symptoms that had subsequently persisted. A subdiaphragmatic esophagogastrostomy was performed. During the following twelve months the patient increased in weight by 15 Kg. and had no difficulty with swallowing. She could eat anything. Roentgen examination nine and fourteen days after the operation showed some retention of the opaque meal in the esophagus but examination four years after the operation showed that the passage through the lower part of the esophagus and the cardia was about as wide as a lead pencil and had an S-shaped course through the diaphragmatic vault. The esophagus was not dilated above the cardia. There was no retention of the meal taken. This case is of particular interest because it is the only case in which the dysphagia has appeared in direct connection with an attack of diphtheria. The second case was that of a man, aged 30, who since childhood had had difficulty in getting food down the gullet. His difficulties had gradually become worse despite prolonged treatment by sound. Subdiaphragmatic esophagogastrostomy was performed and since then the patient has been free from difficulties in swallowing. Roentgen examination also shows the food passing down the stomach without difficulty. Yet in this case the prognosis must be considered fairly serious because of the advanced stage of the patient's pulmonary tuberculosis.

THE PRENATAL TREATMENT OF SYPHILIS

WITH ESPECIAL REFERENCE TO EARLY SYPHILIS IN THE MOTHER[*]

UDO J. WILE, M.D.
Professor of Dermatology and Syphilology, University of Michigan Medical School
AND
JOSEPH W. SHAW, M.D.
Instructor in Dermatology and Syphilology, University of Michigan Medical School
ANN ARBOR, MICH.

On reviewing the literature regarding the question of syphilis and pregnancy, one is impressed by the statistical studies showing the marked reduction of fetal and neonatal death in which the disease is recognized and judicious treatment instituted. Bartholomew,[1] comparing a series of 100 treated syphilitic pregnant women with 100 untreated, found premature births twice as frequent, stillbirths three times as frequent, abortion seven times as frequent, and infant deaths up to ten days after birth nine times as frequent in the untreated as in the treated patients. Armstrong[2] found the stillbirth rate reduced from 24 per cent among the untreated mothers to 6.3 per cent in the treated cases. Ballantyne[3] reported fetal and neonatal accidents in untreated cases to be 606 per thousand, as against 50.7 per thousand in treated cases. McCord,[4] Williams,[5] Welz and Van Nest,[6] and others have reported more or less similar figures.

Other observers have shown in addition that the product of conceptions in a fair majority of cases may entirely escape infection if the mother is treated sufficiently early and vigorously. Beck[7] reported an incidence of 6 per cent of syphilis in the offspring of syphilitic mothers who had received a fair amount of treatment during pregnancy. Williams[8] reported that without treatment 48.5 per cent of the children of syphilitic mothers presented signs of syphilis, while with so-called efficient treatment during pregnancy, only 6.7 per cent of the infants were syphilitic. Marshall[9] reports 35 per cent syphilitic children in the treated cases, as against 78.3 per cent in the untreated. Marshall's cases include only those women in whom the syphilis was less than of five years' duration. Gammeltoft,[10] Belding[11] and others have contributed similar comparisons, but for the most part the percentage of nonsyphilitic children resulting from treated syphilitic mothers, although sufficiently high to be very encouraging from the therapeutic standpoint, has not been as high as recorded by Beck[7] and Williams.[8] Jeans[12] states, without reference to treatment, that 75 per cent of all the offspring of syphilitic families are infected. McCord[4] concludes from a study of 250 pregnant syphilitic women who had been under treatment that "babies born of mothers with serologic evidences of syphilis are syphilitic, and prolonged study and work will prove them so in the majority of cases."

It is of considerable interest to note that an overwhelming majority of the cases studied in these reports were those in which the age of the syphilis was either unknown or at least of several years' duration, and very few presented early clinical manifestations of the disease. Lack of early clinical manifestations in these cases observed could be attributed not only to the age of the infection but also to the fairly well established fact that pregnancy apparently aids the syphilitic defense mechanism in the mother. This was demonstrated experimentally by the work of Brown and Pearce.[13] They found that, when pregnant and lactating rabbits were inoculated with syphilis, only half of the animals developed evidence of primary lesions, while all the controls developed lesions in the usual time. Stokes[14] goes so far as to state that "pregnancy is treatment for syphilis in the woman."

In spite of the inhibitory effects of pregnancy on syphilis, it is probable that in gravid women with early active clinical syphilis contracted about the time of conception, the possibility of a full term living child is rather remote when treatment has not been instituted; and under similar circumstances, the birth of a healthy child is a remote possibility. Under these conditions the statement that "pregnancy is treatment for syphilis in the woman" would appear to lose its force. Whatever protection gravidity gives would appear simply to render the infection for the time being occult.

Since the final outcome of gestation depends so definitely on the age and activity of the infection in the mother, we felt that the efficacy of antisyphilitic therapy in pregnant women could be better evaluated if a group were studied in which the syphilis antedated pregnancy by a short time, coincided with conception or occurred during the gestation. Although our material is comparatively small, we feel justified in presenting this report because of the recent age of infection and the number showing early active clinical syphilis.

This study embraces a series of 100 cases of pregnancy complicated by syphilis in which careful physical examination revealed the patients otherwise in good health. The personnel of this group is made up largely of young girls, the average age being 19.7 years, 65 per cent of whom were unmarried. This high percentage of illegitimacy is due largely to the fact that the University Hospital at Ann Arbor is a state institution and is so situated that these unfortunate girls can be sent in during the early periods of gestation at the expense of the state, and remain in more or less obscurity until after the puerperium.

We felt it of particular interest to note that in this group the average age of the infection at the time of examination was 13.8 months. Apparently 35 per cent contracted their infection at the time of conception, there being a history of but one exposure; 15 per cent contracted their infection two to three months before conception and 5 per cent two to three months after conception, giving a total of fifty-five cases, or 55 per cent, in which infection occurred at or shortly after the time of conception. We observed early active clinical syphilis in forty-two patients of our series, one presenting a primary sore, one presenting a primary with secondary manifestations, and forty with florid secondaries.

BIOLOGIC REACTION

Opinions are at considerable variance as to the reliability of the Wassermann or Kahn tests during pregnancy. That false positives in pregnant women are practically negligible has been shown by Boas, Gammeltoft and Siecke,[15] Stillians [16] and others. It is generally agreed that the strongly positive Wassermann test in the pregnant women, verified on repetition, is diagnostic of syphilis. All are more or less familiar with the false negative in pregnancy. Moore,[17] in his study of 200 pregnant women, of whom 32 had demonstrable secondary syphilis, found that 10 per cent of the latter group were serologically negative. Two years ago the Wassermann reaction was replaced in this clinic by the Kahn precipitation test; hence part of our series is reported in terms of the Wassermann and part by the Kahn test. Of the entire group, the Wassermann or Kahn test on the blood serums was strongly positive in 95 per cent, weakly positive in 4 per cent, and negative in 1 per cent. Those presenting active syphilis were all strongly positive.

PREVIOUS PREGNANCIES

As this group is composed largely of young unmarried women in whom the syphilitic infection was comparatively young, we did not feel the outcome of the previous pregnancies significant. Seventy-six of our series were primiparas; the remaining 24 had had 37 previous pregnancies, in which 16 children were born before infection and consequently were apparently healthy. In the 21 remaining pregnancies, 7 infants came to term, 4 of whom showed definite evidence of congenital syphilis; the other three were not examined by us and hence should be classified as questionable. There were 6 spontaneous miscarriages presumably due to syphilis, and 8 miscarriages induced during the early months by instrumentation. From this it is seen that approximately one third of the total previous pregnancies were syphilized, while one half of those conceived since their infection were syphilitic.

SPINAL FLUID OBSERVATIONS

Lumbar puncture was done on all patients when seen in the early months of pregnancy. We felt that after the sixth month, this procedure was contraindicated because of its occasional abortifacient effect. The spinal fluid of 64 patients was examined, and of these, 51, or 79.7 per cent, were entirely negative; 6, or 9.4 per cent, were strongly positive (by Wassermann or Kahn tests) and showed characteristic changes in cells, solids and the colloidal gold curve; 4, or 6.2 per cent, were weakly positive, and 3, or 4.7 per cent, showed an increase in cells and solids with no other observations. Of the 13 cases showing laboratory evidence of cerebrospinal involvement or invasion, only 2 showed clinical evidence of syphilitic central nervous system disease.

HISTOLOGIC STUDIES OF CORD AND PLACENTA

McCord,[18] from a study of 86 placentas of syphilitic women with no treatment, found syphilitic changes definite and suggestive in 45 per cent, while 55 per cent were essentially negative. The same author,[4] from a study of 192 placentas of treated syphilitic patients, found 28.6 per cent positive, 30.7 per cent "influenced by treatment" and 41.1 per cent negative. Klaften [19] found, on examining a similar group, from 20 to 30 per cent of the placentas showing evidence of syphilis. Of óur series, histologic examination was made on 98 of the cords and placentas by Dr. Warthin, director of the pathology laboratory of the University Hospital. Seventy-one were reported negative, 12 as showing definite evidence of syphilis and 15 as being suspicious or suggesting a healed syphilitic process. Of the 27 placentas reported as being syphilitic, all but 2 of the blood specimens taken from them at birth were reported positive by the Wassermann or Kahn tests.

TREATMENT

Treatment was instituted in the form of intravenous asphenamine, followed by mercury inunction, immediately on recognition of the disease. The average time for beginning treatment was about the nineteenth to the twentieth week of pregnancy. Each patient had a complete physical examination and urine analysis. If there were no contraindications, the patients were hospitalized and kept under careful observation following each injection, so that we felt that fairly intensive courses could be given with the least possible danger to mother and fetus. Most of our series (82 per cent) received *arsphenamine*; the remaining

[19] Klaften, E.: Die Prinzipien der antisyphilitischen Behandlung der Schwangeren, Arch. f. Gynäk. **135**: 620 (Feb. 11) 1929.

18 per cent received neoarsphenamine. Courses were given with from three to six injections in a course and an interval of from one to three months allowed between courses, during which time mercury was administered in the form of the inunctions. Our patients averaged 2.2 Gm. of arsphenamine, which is approximately the amounts given by Marshall,[9] Beck,[7] McCord [4] and others. Amounts given by Bartholomew [1] were considerably lower. Some of our patients received as much as 4 Gm. of arsphenamine during pregnancy, and none showed untoward effects as a result. The average amount of mercury for the group was a course of thirty-five inunctions.

The treatment of syphilis during pregnancy, like the treatment of syphilis under other conditions, is a much debated question. We feel that, in view of the extra burden of pregnancy thrown on the parenchymatous organs of the mother, even a greater attempt at treating the patient rather than the disease should be made than is advocated for the treatment of syphilis alone. For this reason rigid criteria of treatment should be avoided and each patient considered as a therapeutic problem to be solved according to the indications and contraindications.

We observed no reaction of any import that could be attributed to the intravenous administrations of arsphenamine. Gammeltoft,[10] Stokes,[14] Bartholomew,[1] McCord [4] and others agree that, if the patient is kept under careful observation and the drug cautiously given, reactions are almost negligible. Buschke [20] considers abortions from arsphenamine frequent during the first part of gestation. We failed to observe any definite relationship between intravenous arsphenamine and miscarriage or abortion.

Under our therapeutic regimen, there were delivered from the 100 syphilitic women 92 living babies, of whom 7 were premature and 85 were full term. Of the remaining 8, 3 were premature stillbirths, 2 were full term stillbirths, and 3 were born prematurely but lived only a few hours. Of the 8 ending disastrously, all showed evidence of syphilis at the autopsy table. Six of the latter group were the products of apparent conceptional syphilis.

The Wassermann or Kahn tests were done on the cord blood of the 92 living children. Forty-four were reported as strongly positive, 17 as weakly positive and 31, or 33.7 per cent, as negative.

The early diagnosis of syphilis in the living offspring of treated syphilitic women is extremely difficult. Very few of these infants show definite clinical evidence of the disease at birth and a certain percentage fail to show serologic evidences, and yet if allowed to go untreated the disease may manifest itself within the first few months while others may go on to puberty and even after before developing diagnostic signs. Obviously this problem presents two aspects: first, the stand taken by Welander,[21] Beck [21] and others, that every child born of a syphilitic mother should receive antisyphilitic therapy whether or not it presents clinical or serologic evidence of the disease, and, secondly, that only those should be treated that present definite diagnostic criteria, as advocated by Gammeltoft,[10] Ahmann,[21] Almkvist [21] and others. As we were dealing with a group of irresponsible young girls in whom the infection was young, we were inclined to take a middle stand and treat every infant in whom we felt there were positive or suggestive evidences of the disease. Basing our diagnosis on (1) general examination of the infant, (2) cord blood and infant blood Wassermann or Kahn tests, (3) placental involvement and (4) the activity and age of the syphilis in the mother, we found that 26 of the 92 living infants apparently had escaped infection, while 66 fell in the group we considered should have immediate antisyphilitic therapy.

TREATMENT OF INFANTS

Treatment was instituted in these 66 cases within the first two weeks of life. This consisted of six weekly intravenous injections of neoarsphenamine. (Those in whom venipuncture could not be done received six intramuscular sulpharsphenamine injections at weekly intervals.) They were all observed over a period of from seven to eight weeks following birth, during which time they were found to tolerate the drug, and they gained weight well within normal limits. Following the sixth injection, the infants were discharged with either mercury with chalk, to be taken by mouth, or mercury in the form of inunctions. The untreated or apparently nonsyphilitic group were observed for a variable period of from four to eight weeks. If nothing developed at the end of this time, they were discharged and the mother was instructed to report here or to her home physician at the end of three months for observations and repeat serologic examinations.

*Outcome of Pregnancies from One to Five Years After Delivery**

	Treated	Untreated	Total
Number of cases	66	26	92
Children living and apparently well, 1-5 years	52	19	71
Children living at end of second month (never heard of again)	8	5	13
Children died of syphilis	1	2	8
Children died of pneumonia	3	0	
Children died, cause unknown	2	0	

* Reports obtained with the help of the social service department.

Total traced, 79; of these, 71, or 89.8 per cent, were living and apparently well from one to five years later.

Infants in whom we felt there were positive or suggestive signs of congenital syphilis were given six weekly intravenous injections of neoarsphenamine.

Few of these patients have returned for observation or further treatment, so that a proper evaluation of our neonatal treatment cannot be made. However, during the past three months, with the aid of our social service department, we have attempted to trace these infants. Questionnaires were sent out inquiring as to the present status of the children.

The table as nearly as could be determined shows the end-results of our labors. Of the ninety-two living births, two of those alleged to be nonsyphilitic developed acute syphilis and died within the first three months of life. Of the treated group, three died within the first year, two of pneumonia and one of syphilis; one died the second year and one the third year, cause unknown, while another died the third year of pneumonia. Seventy-one of these children were living and in apparently good health, from one to five years after birth. Thirteen could not be located. So that of the seventy-nine infants traced, 89.9 per cent were living from one to five years afterward. We attribute this high percentage of infants surviving the first few years of life largely to the combined prenatal and neonatal treatment.

CONCLUSIONS

1. Prenatal treatment of early syphilis results in a marked decrease of the feticidal effects of the disease.

2. A slightly higher percentage of syphilitic babies occurred in our group than has been recorded by others.

---

[20] Buschke, quoted by Klaften (footnote 19).
[21] Quoted by Gammeltoft (footnote 10).

This higher figure is readily accountable to the earlier age and the activity of the syphilis in our series.

3. Arsphenamine is well tolerated by gravid women, and there is no apparent relationship between the intravenous administration of the drug and miscarriage or abortion.

4. Prenatal treatment modifies definitely the syphilitic changes in the placenta.

5. Regardless of the absence of clinical or serologic observations, it seems wise to treat babies born of mothers in whom the syphilis is early to supplement the prenatal treatment of the mother.

ABSTRACT OF DISCUSSION

Dr. Carroll S. Wright, Philadelphia: I have been struck during the past several years with the apparent decrease in congenital syphilis. For seven years I have had charge of the congenital syphilis clinic in the Philadelphia Graduate Hospital, and recently have had difficulty in obtaining sufficient cases with active manifestations for teaching demonstration. I have had only two cases with cutaneous lesions referred to me from the obstetric clinic of the same hospital, and am inclined to believe that there is a marked decrease in the number of such cases. I attribute this to two causes; first, the marked improvement in treatment; second, education of the public. I am strongly in favor of such campaigns as are being carried out now by the Metropolitan Life Insurance Company and other organizations. The advertisement of the insurance company emphasizes the importance of antenatal therapy in pregnancy complicated by syphilis. My interest being stimulated by Drs Wile and Shaw's forthcoming paper, I asked my secretary to get out for me all histories of patients with syphilis complicating pregnancy for three years back. By a curious coincidence I had 100 case records, a number paralleling Dr. Shaw's, showing nine stillbirths during that period. None of the patients had any treatment previous to the fifth month, which I believe represents the deadline of effective therapy. I was further interested in that we found about 60 per cent of positive cord Wassermann reactions, although I always have had some doubt as to the significance of the cord Wassermann test. I do not think the advantage of early therapy can be overlooked. As an example of what therapy can do, I will describe a case: A patient gave birth to a seven months' macerated fetus. Following this she was referred to our clinic and received one neoarsphenamine and four bismuth injections. She then disappeared and exactly nine months later came into the hospital and gave birth to a healthy, normal appearing infant. The cord Wassermann reaction was positive. I have followed that child for four years and have never seen any sign of syphilis. A minimal amount of therapy in this case changed the whole picture, although I realize the inadequacy of such therapy in most cases.

Dr. Charles C. Dennie, Kansas City, Mo.: I am much interested in the subject of prenatal treatment of syphilis. We have carried out this idea in the Kansas City General Hospital and in the University of Kansas for many years. I agree with Dr. Wright but go a little further and will say that in my opinion the fourth month of pregnancy is the deadline of effective therapy. This is the reason that, when autopsies are done on congenitally syphilitic children, the epiphyses of the bones is the one place where evidence of this disease is nearly always found. That is one landmark that pathologists look for. I think the involvement begins here as soon as the bones begin to form and therefore I think that, in order to be successful in the treatment of these cases and to prevent stigmas which later may occur, antisyphilitic treatment should be instituted before the fourth month of pregnancy. I believe that, if the treatment is instituted at the seventh or eighth month of pregnancy, in the course of events if the child was to have the stigmas of syphilis he would have this even though the blood was found to be negative and remained so for several years after birth. I think the treatment should be largely arsenical, for arsenic is the only thing that has an influence on the spirochetes involving the bones and joints. If treatment is started before the fourth month it is entirely possible to give fifteen or sixteen doses of arsphenamine and the hazard is very small in this type of treatment. It is true that a few doses of arsphenamine, even in the seventh or eighth month of pregnancy, will greatly cut down the number of stillbirths or prenatal deaths, but if a small amount of treatment is given to the mother it will be just enough to change the Wassermann reaction to a negative but not enough to eliminate the syphilis from the child, so that in three or four years the child may develop a positive Wassermann reaction or some manifestation of syphilis accompanied by a negative reaction. One often sees an infant with a negative Wassermann reaction at birth whose mother had a small amount of treatment before the birth of the child. I can call to mind three such cases; in all, there were enlarged bones and spleens. Institution of active treatment caused a great reduction in the size of these organs. There is no reason why an infant in utero should respond to indifferent treatment. The fact that a little treatment will produce a living child is an interesting observation but a dangerous procedure.

Dr. Joseph Earle Moore, Baltimore: I am inclined to think that it would be extremely wise for us as individuals who come in contact with pregnant syphilitic women to emphasize the observations to obstetricians rather than to ourselves. Our country, as compared with European countries, is backward in this way. In Denmark, where the use of the routine Wassermann reaction is much more prevalent, there are only about sixty children with congenital syphilis in the whole country of three and one-half million inhabitants. This seems strange but it shows what can be accomplished in the treatment of these women, when properly carried out. Dr. Williams of our obstetric department has been greatly interested in this subject and has been carrying out the Wassermann reaction on his patients for something like fifteen years. In spite of the fact that most obstetricians are thoroughly convinced of the value of routine Wassermann reactions for clinical patients, they are not yet convinced so far as patients in private practice are concerned. The average obstetrician feels that to carry out routine Wassermann reactions in private practice would be to insult his patients. In my small private practice I have forty examples of congenital syphilis among well-to-do families. I have been greatly interested in the effect of pregnancy on the suppression of the lesions of syphilis, and I note that the authors assume that 55 of their 100 patients had acquired syphilis at or about the time of conception. I wish to know whether this had any effect on the type of lesions the patients presented at the time of examination. The question of the deadline of therapy has been introduced into the discussion and I wish to take sharp issue with what has been said. I do not believe that the deadline is at the fourth or the fifth month. I think much can be accomplished by treatment given as late as the eighth or ninth month, and think it is never too late to treat the syphilitic woman. I wish to know what value is attached to positive cord Wassermann tests, and what influence this had on determining whether or not such patients should be treated for syphilis. I should also like to ask whether the statement that these children are well after five years is based on the absence of symptoms or a negative Wassermann test.

Dr. James R. McCord, Atlanta, Ga.: For several years I have had under observation from 1,500 to 2,000 pregnant women with syphilis. I have performed necropsies on more than 1,000 babies. I have paralleled this with a Levaditi stain of all the organs, have examined all the bones by the roentgen ray, and have done many dark field examinations. I believe that in the light of our present knowledge it is well to teach that congenital syphilis is always the result of syphilis in the mother. The time of infection of the mother has something to do with infection in the child. I am inclined to believe that syphilis is the cause of abortion. I have never found syphilis in a fetus that weighed less than 100 Gm. It is better to try to prevent the disease in the child than to cure the mother during pregnancy. I give the mother 0.45 Gm. of neoarsphenamine and a mercurial inunction weekly until the baby comes. I have treated many of these cases with only one fatality, and that was the result of error. I have reported several hundreds of these cases. A positive Wassermann test properly carried out is just as much a sign of syphilis in a pregnant as in a nonpregnant woman. A negative Wassermann reaction on the cord means nothing, but a positive reaction means syphilis. About 93 per cent of the cases with positive cord examinations without treatment end disastrously. Those cases in which more than six treatments were given ended disastrously in only nine instances. Treatment during pregnancy definitely influences the microscopic appearance of the placenta. I have found bone evidences of syphilis in 51 per cent of our autopsies. This is an osteochondritis; the periosteal type was found in only 2 per cent. The organisms of syphilis were found in 35 per cent of the autopsies. My last series reported of pregnancy with syphilis, without treatment, ended disastrously in 80 per cent; with less than six treatments, 34 per cent; with more than six treatments, 9 per cent.

Dr. David Lieberthal, Chicago: In thirty-five years of experience in treating prenatal syphilis I have relied mainly on mercurial inunctions. And here must be made a division of time in two periods: the one preceding the newest discoveries in the diagnosis and treatment of the disease, and the other since then. In dispensary practice, patients could not be followed up regularly. They were properly instructed how to carry out the treatment and to report regularly. In most instances they had to apply the rubs themselves. As was to be expected, only a certain percentage could or would follow the plan to the end; therefore, final results could not be recorded. In those, however, who did continue the treatment, the results were gratifying. In private practice, conditions were more favorable as the cooperation of the patients was more easily assured. The treatment of all these patients, dispensary as well as private ones, consisted in courses of inunctions with intervals of from two to three weeks until from six to eight weeks or less before termination of pregnancy. The inunctions were carried out by trained masseurs whenever possible. With the advent of the newest discoveries and with subsequent thorough organization of clinics with follow-up systems the management of prenatal cases at my clinic has been quite similar to that of Drs. Wile and Shaw, neoarsphenamine in small doses, 3 Gm. in all, followed by or in combination with inunctions as outlined. The same plan has been carried out in my private practice. I have watched the majority of private cases for all these years and followed up the second and third generation. Ultimate results have been very gratifying.

Dr. Joseph W. Shaw, Ann Arbor, Mich.: Dr. Wright stated that he has seen few cutaneous manifestations of syphilis in the new-born. In our series we had only one case. Regarding the treatment of the pregnant syphilitic woman, although this series received largely old arsphenamine intravenously and mercury in the form of the inunction, during the past year this clinic has used, for the most part, insoluble bismuth salts and old arsphenamine. The point that was brought out as to the deadline for treatment is interesting. We feel that treatment is efficacious up to the time of birth, and we attempt to institute treatment as soon as the disease is recognized and continue it right up to the ninth month, and even in those cases we have observed very few reactions. I think that, as Dr. Dennie said, if treatment is begun before the fourth or fifth month, the results may be expected to be better. We did not attach much significance to the cord blood. We feel that positive observations in the placenta are much more important criteria in the diagnosis of congenital syphilis. Regarding the infants we reported, apparently living and well from one to five years after birth, as stated, this report was made with the help of the social service department. We were unable to reexamine the majority of these youngsters after their discharge from the hospital and can not state definitely whether the blood was negative or positive. We can only present the reports of the social service workers in the various communities, namely, the number living and apparently well. The question as to whether it is necessary to treat these patients during every pregnancy has been considered and we feel that probably during the first several years of the disease treatment should be instituted during pregnancy. However, as the disease becomes older in the mother, each patient should present a therapeutic problem in itself, and no definite therapeutic standards can be laid down.

OBSERVATIONS OF A LARYNGOLOGIST *

R. C. LYNCH, M.D.
NEW ORLEANS

I practice otolaryngology. My observations are entirely clinical. Some of them may interest some of you: for instance, vocal nodules, either in young children or in adults, a retention cyst, and the earliest manifestation of cancer are the only tumors that grow from the free edge of the vocal cords. Fibroma, angioma and their combinations, pedunculated tumors of various types, all start on the under or the upper surface of the cord; this is also true of hemorrhagic blebs. Contact ulcers are the results of excessive abuse of the voice during acute inflammatory reaction. All other ulcers are of special etiology. A simple chronic ulcer never occurs in the larynx; its etiology must be sought for.

Single pedunculated papilloma in the child is different in its behavior from the multiple type; the prognosis is better. Dissection with the aid of suspension gives me the best results. The same tumor in the adult is practically always malignant; in my experience it should be thus regarded. Careful microscopic dissection or serial section has always shown at some part of the tumor mitotic figures with lawless cell proliferation.

I have made the mistake a number of times of believing the report on one microscopic section. Clinically I have been made to change my mind. The reports on a series of sections are more trustworthy.

Again, pedunculated papillomas of the tonsil soft palate are not the same clinically as those referred to and show no such tenacity as the multiple type; these two are different. Clinically, multiple papillomas presumably originate from the papillary layer of the mucous membrane; they will recur on scar tissue, they are autografting, they are contagious, and they are said to disappear spontaneously. I have never seen this, though the appearance of a crop on the back of the hand preceded a marked improvement in the larynx. No one remedy or technic yet suggested will cure all cases. I have tried every plan. My experience covers 203 cases. If reports as to recurrence were delayed, the results would in most instances not be so flattering.

My greatest surgical contradiction is a patient on whom I have operated ninety-six times for papilloma of the larynx. Some day I shall report his case in detail.

The earliest carcinoma of the larynx springs from the middle third of the vocal cord. Twenty-six cases are recorded, all verified by microscope. Twenty-five of the patients are well without recurrence from two to eighteen years after suspension and dissection. I have ninety-eight cases in which proliferation extended through the basilar membrane so as to make the cord lag but not fixed. Seventy per cent of the patients are well without recurrence, though lately one had cervical metastasis and died seven years after operation, and the other had intestinal metastasis after four and one-half years.

When the cord is fixed by the growth, only a laryngectomy is indicated; 152 laryngectomies have been done, with two deaths from heart block within ten days of operation. Sixty-two per cent of the patients are well without recurrence, which takes place usually within

---

* Chairman's address, read before the Section on Laryngology, Otology and Rhinology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

eighteen months. A patient who is well four years after a laryngectomy is, so far in my series, practically cured, though I believe one should be cautious in the use of this word as applied to cancer.

Eight cases of metastasis to the lung have been observed in truly intrinsic cases, all discovered by accident, four substantiated by autopsy. Routine roentgen examination of the chest must be done before operation. Two cases of coincident carcinoma of the esophagus, and one of the soft palate and tonsil and larynx, have also been observed.

Diathermy coagulation under suspension is of real value in properly selected cases; chloroform is used. I have yet no reason to change my gas, oxygen and ether anesthetic for this work, when diathermy or the cautery is not used.

All laryngectomies are done in one stage. Primary healing has risen to better than 12 per cent. Plastic operations for closure of the esophagus amount to 3 per cent. Caloric feeding through the esophageal tube is essential for maintenance of weight and resistance. About 50 per cent develop tonal voice. An artificial larynx is very practical.

Biopsy should be done only if operation is agreed to; under this plan, no evidence of harm thus far occurred.

Deficiencies in diet, allergic states, endocrine unbalance and low akinetic exposure form the etiologic quadrad of sinus disease in children; any one, any combination or all four may be the fault. Infection with pathologic change may exist even when the quadrad seems normal. Window resection for drainage and ventilation will not suffice in every instance, but persistence and patience must be practiced before radical procedures are proposed.

The same outline stands for adults, though here one is more likely to see only end-results of long continued etiologic factors. Teeth add another source. In adults with pan sinus disease demanding radical operation, the antrum should be attended to first. Preservation of the periosteum over the frontal plate, plus incision in the bone not above the orbital ridge is the best guard against osteomyelitis. My technic strictly adhered to still gives me the best results, and many other operators are duplicating these.

Malignant nasopharyngeal tumors are significant for lack of rhinologic symptoms. Pain in the face, trismus, tinnitus with stuffy progressive deafness and single or multiple cranial nerve involvement calls for most careful scrutiny.

Salivary calculus will resemble sarcoma or mixed tumor disease.

Diathermy will light up and produce progress toward increased deafness in otosclerosis.

Sinus thrombosis is comparatively rare, far south.

The inferior turbinate is an essential organ on the coast line, and especially far south. Any procedure that recommends its partial or complete removal will be followed by accumulations and changes resembling atrophy.

The wide nose of the Negro with its large turbinates will mislead the uninitiated. The greater the dilution with the white race, the less is the resistance. In Negroes the tissue reactions to inflammation are the same as observed in the white race. Skin incisions are likely to be followed by keloid scar.

Allergic reactions are scarce in real Negroes, who seem less sensitive. They make good patients.

632 Maison Blanche Building.

ADDITIONAL LIGHT ON THE DYSMENORRHEA PROBLEM *

NORMAN F. MILLER, M.D.
Professor of Obstetrics and Gynecology, State University of Iowa College of Medicine
IOWA CITY

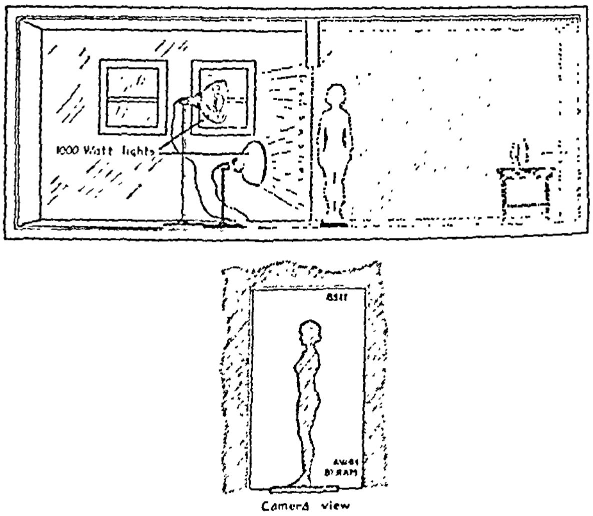

Fig. 1.—Method of obtaining silhouettes.

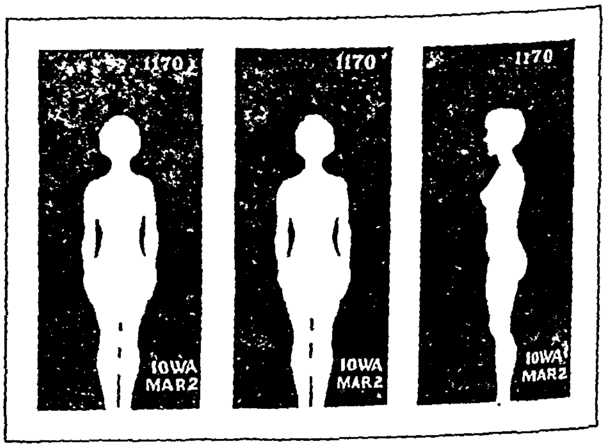

Fig. 2.—Appearance of silhouettes.

Discoveries and real contributions in modern medicine have not been numerous; yet a few, by their brilliance, have lent a happier color to many unsettled problems that physicians must face. Among the latter, dysmenorrhea must be included. Contributions covering the histology of menstruation,[1] and the elaborate studies on ovulation [2] and the female sex hormone,[3] have helped considerably in clearing away the haze surrounding this physiologic process. Yet in some respects dysmenorrhea remains as much of a riddle today as it was fifty years ago. The truth of this statement is well illus-

trated by a comparison of earlier conditions with our own. Thus, in 1877, Jacobi[4] noted that 46 per cent of women complained of menstrual pain; and in 1927, fifty years later, in a study of 785 young college women and nurses, we found 47 per cent similarly afflicted. Of this number, however, only 17 per cent had pain sufficiently severe to require rest in bed or limitation of activity. Regardless of probable decrease in the incapacitating forms, the fact cannot be evaded that dysmenorrhea remains today an important economic and medical problem.

TABLE 1.—*Individuals Requiring Rest in Bed in a Series of 429 Cases of Dysmenorrhea*

Duration of Bed Rest	Number	Per Cent of Dysmenorrhea Cases	Per Cent of Total
Hours	83	19	10
Days	58	14	7
Total	141	33	17

On the whole, medical treatment of menstrual pain has been unsatisfactory. Temporary improvement is readily accomplished, but desirable permanent relief seldom rewards even the most diligent efforts along this line. From time to time those interested in physical education for women have reported apparent benefit associated with simultaneous improvement in posture. As a group, physicians have paid little attention to these reports, thinking possibly that it is simply another method of dodging the question.

Failing to achieve satisfactory results with available methods, and stimulated by the optimistic reports of those interested in the teaching of physical education in our universities and colleges, we determined to learn, if possible, the relationship existing between faulty body mechanics and common gynecologic complaints, especially dysmenorrhea. Using the girls of the entering classes at Wellesley College, the University of Iowa, and the Nurses Training School at the University of Iowa as subjects, we commenced the study in the fall of 1927. In all, 785 young women were available for study.

METHOD OF STUDY

Each girl was subjected to the usual physical examination required for admission, and in addition was qualitatively classified as to posture and muscle tone. At Iowa, a permanent record of the lateral and anterior aspects of each individual was obtained in such a manner as to resemble the usual silhouette, but without the distortion associated with silhouettography.

TABLE 2.—*Ability to Take Exercise Among Patients Having Dysmenorrhea*

Type of Exercise	Number	Per Cent of Dysmenorrhea Cases	Per Cent of Total
No exercise	30	7	4 } 17
Mild	104	25	13 }
[illegible]	229	53	29
	61	14	8
	5		
Total	429		

The method is clearly illustrated in figures 1 and 2 and requires no explanation.

A similar method is used at Wellesley. Posture and muscle tone ratings were determined from study of the nude individual and shadow pictures, by more than one trained person well qualified in the work of objective grouping on a posture basis. All subjects were directly questioned concerning dysmenorrhea and the replies noted on cards specially prepared for this purpose (fig. 3). In noting the presence or absence of menstrual pain, the need for rest in bed and the limitation of activity at the period time, a triple check was obtained which also permitted classification of dysmenorrhea into groups, depending on the severity of the symptom.

Fig. 3.—Questionnaire and follow-up record.

The questionnaire is self-explanatory and requires no comment.

Since the beginning of the study in 1927, check up examinations have been made in 1928, 1929 and 1930, by an examining staff which with few exceptions has remained intact since the beginning of the study. It was planned to incorporate the 1930 observations in this report, but difficulty and delay in collecting the data made this impossible. Although the number of cases dwindled to 495 in 1929, it is hoped that when the four year study is completed the number will be sufficient to permit satisfactory analysis.

[4] Jacobi, Mary P.: The Question of Rest for Women During Menstruation, New York, C. P. Putnams' Sons, 1877.

OBJECTIONS TO METHOD

Throughout this work we have been conscious of certain definite objections to the method of study employed, none of which can readily be eliminated. The complete reliance on objective observation, and the noticeable lack of methods of precision form the principal drawbacks. While posture types are fairly well established and permit ready qualitative grouping, their corollary, muscle tone, is still only vaguely understood, and attempts at classification are unsatisfactory. Muscle tone is probably more fundamental than posture, but adequate definition and methods of measuring are conspicuous by their absence.

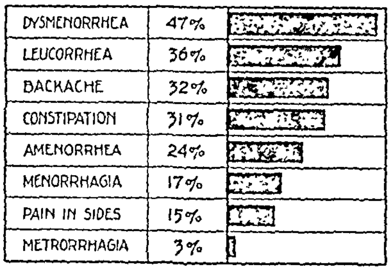

Fig. 4.—Incidence of gynecologic symptoms noted on original examination in 1927.

Lack of careful pelvic examination is another objection that has been eliminated in new studies recently commenced. Since most of the individuals in the present group are generally healthy young women, we have assumed the pelvic organs to be relatively normal.

Diet, climate, environment and glands of internal secretion may be mentioned as other factors deserving consideration. As we were aware of these drawbacks, every effort was made to minimize their importance, data being obtained by the best available methods with sufficient check to reduce the personal equation to a minimum. Even so, the observations here presented must be viewed in the light of possible relationship rather than proved facts.

Since the plan is to make this a four year study, no detailed discussion will be attempted at this time, the purpose being simply to present data covering the study to date, from which the reader, if he so desires, may draw his own conclusions.

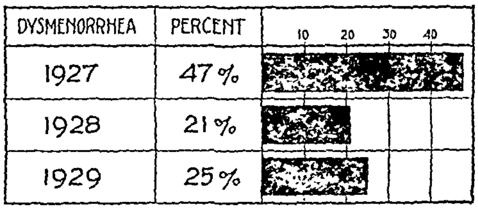

Fig. 5.—Incidence of dysmenorrhea.

RESULTS OF STUDY

The incidence of common gynecologic symptoms in this group at the time of original examination is shown in figure 4. Should final analysis warrant, the other symptoms will be considered at some future date.

The trend of dysmenorrhea for the years covered by this study is revealed in figure 5. The improvement noted includes completely relieved cases as well as those showing definite improvement since the first examination in 1927. Figure 6 indicates the general relationship between posture, muscle tone and menstrual pain. It will be noted that with the decrease in dysmenorrhea there has occurred a reduction in the poorer grades of posture and a simultaneous increase in the better grades. The ratings for muscle tone, while showing much the same relationship, appeared generally high at the original examination, probably because of inexperience in determining this factor. Whether these observations indicate possible cause and effect relationship can be determined only by consideration of the various groups.

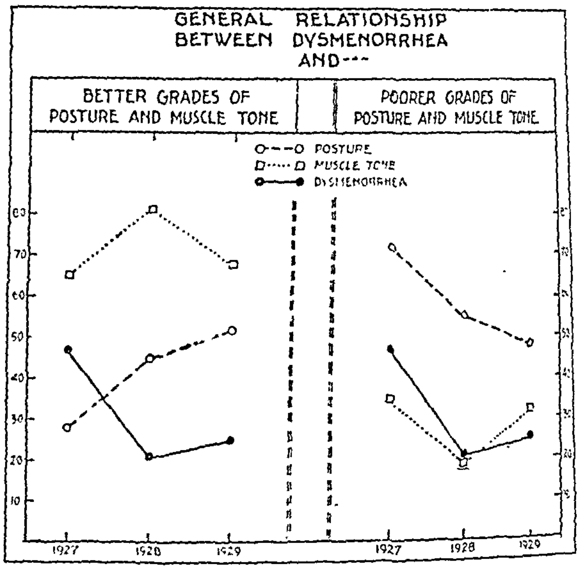

Fig. 6.—General relationship between dysmenorrhea and posture and muscle tone.

Completely Relieved Cases.—Of the 495 subjects with complete records for the years covered in this study, 237 had dysmenorrhea in some form at the time of the original examination in 1927, and of these 127 were completely relieved by 1929. Forty-eight, or 38 per cent, of this number originally had severe pain as indicated by the necessity for limited activity or rest in bed at the period time. The remaining seventy-two, or 62 per cent, had a mild type of dysmenorrhea.

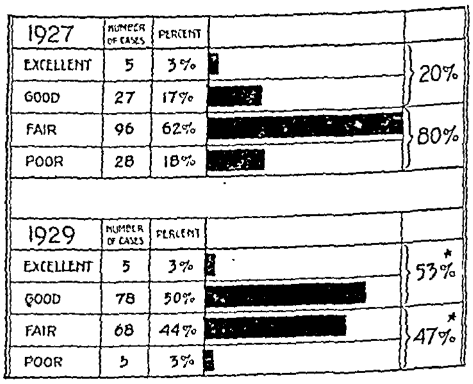

Fig. 7.—Posture in cases presenting dysmenorrhea in 1927 but none in 1929: an increase of 33 per cent in the better grades of posture and a decrease of 33 per cent in the poorer grades.

Greatly Relieved Cases.—Twenty-nine of the 237 dysmenorrhea cases were greatly improved at the end of the period under consideration, twenty-one, or 72 per cent, being severe and eight, or 28 per cent, mild in character.

The fact that 43 per cent of the relieved or improved group had severe dysmenorrhea originally is significant and should dispel any suspicion that only the milder cases were benefited. The relationship between posture and muscle tone in individuals showing complete relief or marked improvement is shown in figures 7 and 8.

Unimproved Cases.—Of the 237 cases of dysmenorrhea in 1927, 81, or 34 per cent, failed to show any improvement. Figures 9 and 10 reveal the posture and muscle tone grouping in these cases for 1927 and 1929. A gain in the better types of posture is noted in this group, whereas the muscle tone ratings reveal a slight decrease. In both posture and muscle tone, however, the poorer types predominate both at the time of the original examination and again in 1929. Interpretation of these observations is complicated by our lack of knowledge concerning the number with primary dysmenorrhea.

1927	NUMBER OF CASES	PERCENT		
EXCELLENT	48	31%		77%
GOOD	72	46%		
FAIR	31	20%		23%
POOR	5	3%		
1929	NUMBER OF CASES	PERCENT		
EXCELLENT	37	24%		70%
GOOD	72	46%		
FAIR	40	26%		30%
POOR	7	4%		

Fig. 8.—Muscle tone in cases presenting dysmenorrhea in 1927 but none in 1929.

Cases Without Dysmenorrhea.—Two hundred and fifteen individuals had no dysmenorrhea in the fall of 1927 or in 1929. The relationship between posture and muscle tone in this group is shown in figures 11 and 12. The increase in the better types of posture in this group may explain the absence of acquired dysmenorrhea but complicates the explanation on a basis of posture. Quite a different situation, however, is seen in the ratings of the muscle tone. In 1927 and 1929 over three fourths of this group without dysmenorrhea had desirable muscle tone, a finding that becomes even more significant when compared with the figures in the dysmenorrhea cases, and one which suggests that muscle tone, which after all is more fundamental than posture, may in some way be responsible for many instances of menstrual discomfort.

1927	NUMBER OF CASES	PERCENT		
EXCELLENT	5	6.2%		28.4%
GOOD	18	22.2%		
FAIR	35	43.2%		71.6%
POOR	23	28.4%		
1929	NUMBER OF CASES	PERCENT

GOOD	21	26%		
FAIR	34	42%		56%
POOR	11	14%		

Fig. 9.—Posture in unimproved cases.

Acquired Dysmenorrhea.—Figures 13 and 14 indicate the posture and muscle tone groupings in the forty-three cases of acquired dysmenorrhea. Twelve of the forty-three subjects improved from undesirable to desirable posture, four changed in the reverse direction, seventeen continued the same, and the remainder varied only[5] within their respective groups. Seven changed from undesirable to desirable muscle tone, seven made the change in the reverse direction, seventeen remained the same, and the others made minor changes[5] within their respective groups. Interpretation of these observations is impossible since no information concerning acquired pelvic infection and general disease is available. On the other hand, it is worthy of note that the undesirable posture grades were in the majority both in 1927 and again in 1929.

RELATIONSHIP BETWEEN FAULTY BODY MECHANICS AND DYSMENORRHEA

While it cannot be said that faulty posture or poor muscle tone causes dysmenorrhea, our study reveals a decrease in the occurrence of dysmenorrhea coincident with improvement in posture and muscle tone. This improvement occurred during a time when the method of living could scarcely be considered conducive to restfulness and quiet. Indeed the long, irregular hours, the strain of study and examination, would seem quite enough to increase any neurotic tendencies present in these individuals. During this time the only remedial measure was the course in physical training and corrective exercises. Explanation of this possible causative relationship is better understood by preliminary consideration of certain related facts.

It is conceded that the tone of the skeletal muscles serves as a good index to the tone of the circulatory system, and consequently individuals with poor skeletal muscle tone may be said to have poor tone of their circulatory systems. The significance of this becomes evident when it is recalled that the pelvic organs are abundantly supplied with blood vessels, the veins forming an extensive interlacing network through anastomoses between the pampiniform, uterine, cervical, vaginal, bladder and hemorrhoidal plexuses. These veins are characteristically thin walled and except for those of the uterus receive their chief external support from intra-abdominal pressure (figures 15 and 16). They are also distinctive in that they and the large veins into which they empty do not have valves as do the veins of the legs. In the quadruped these points are of little significance, while in the biped or human being they may be important in the explanation of certain pelvic symptoms. Roughly, the total blood volume of the body may be divided into quarters, one quarter being in the peripheral circulation, one quarter in the heart and lungs, and the remaining half in the portal circulation and other abdominal organs. In the quadruped most of the blood volume is near the heart level and consequently no excessive strain is placed on the vascular system (fig. 17). In the biped, or human being, however, most of the blood is below the heart level and the circulatory system is subjected to considerable strain. So long as the muscular tone of the body is good, no untoward effects are noticed; but with the loss of tone, distressing symptoms may arise. Because of their location in the most dependent portion of the peritoneal cavity and because of the presence of numerous interlacing thin walled valveless veins, the generative organs are particularly susceptible to conditions causing congestion. Doubtless the frequent occurrence of varicose veins in human beings and their scarcity in quadrupeds is a clinical manifestation of this relationship.

Fig. 14.—Muscle tone in cases of acquired dysmenorrhea.

The physiologic changes occurring at the time of the normal menstrual period must also be considered. The first or premenstrual stage lasts from seven to ten days and is characterized chiefly by congestion of the pelvic organs. When the hyperemia of the uterine mucosa reaches the breaking point, hemorrhage occurs into the surrounding tissues by rhexis and diapedesis. This inaugurates the second or desquamative stage, characterized by loss of the surface epithelium from the uterine cavity and the onset of the menstrual flow. Normally this stage is thought to last about two days, following which the third or regenerative stage begins, when regeneration or rebuilding of the endometrial glands takes place and is generally complete in four days. The resting interval follows and lasts from ten to fourteen days, when the next premenstrual stage appears.

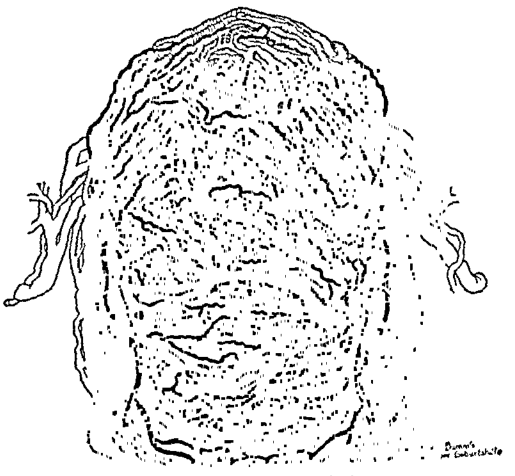

Fig. 15.—Vascular network of the uterus.

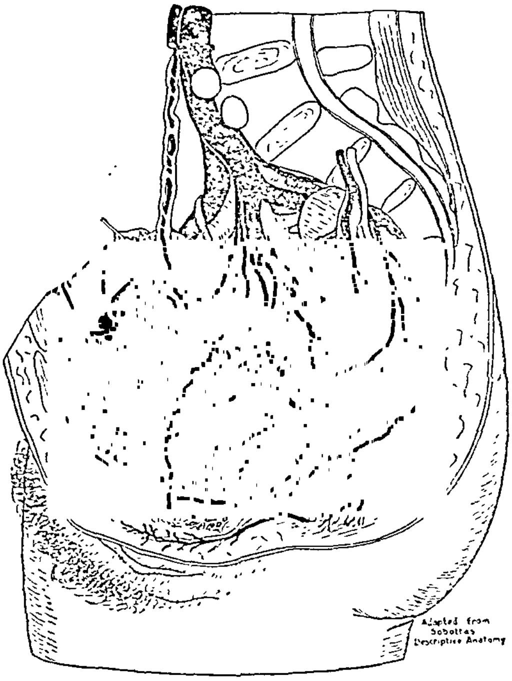
If lack of muscle tone plays a part in causing dysmenorrhea, one might justly expect the discomfort to begin before or with the onset of the menstrual flow and to cease as soon as the congestion subsides or the pelvic organs are depleted. In the majority of cases this is exactly what happens (table 3 and fig. 18). Apparently the superimposing of the physiologic congestion of menstruation on the already congested pelvic organs is more than the structures can comfortably tolerate, and the dull steady pain characteristic of congestion is the result.

Those who favor neuroses as a basis for dysmenorrhea must explain the paradoxic improvement under circumstances that tend to increase neurotic tendencies. The situation, however, permits of a satisfactory explanation on the basis of faulty muscle tone, for it is well known that high strung or nervous individuals have better tone than do the phlegmatic type.



Adapted from Sobotta's Descriptive Anatomy

Fig. 16.—Anastomosis of vascular plexuses in the pelvis.

Additional evidence favoring the muscle tone theory is to be found in studies of parous women, in whom the average posture and muscle tone is generally low. In a review of 200 multiparas without evidence of infection, all of whom had had two or more children, it was found that 44 per cent had dysmenorrhea. In most cases this was of the congestive type, the pain beginning before or with the flow and disappearing within the first day after the onset. Since primary dysmenorrhea may be excluded in parous women, it appears that the incidence of the secondary types is actually higher than among the young women forming the basis of this study, where the primary type could not be eliminated.

	46	5
	18	2
Sixth day	6	

SUMMARY

It may be well to repeat that while it is not justifiable to conclude that faulty posture and poor muscle tone cause dysmenorrhea, a reduction in menstrual pain has occurred along with a decrease in imperfect posture and poor muscle tone as a result of directed physical exercise. Moreover, this occurred during a period when the living regimen could scarcely be considered quieting or conducive to restfulness, and, finally, when the only actively and knowingly applied remedial measure was the required course in physical education and corrective exercises. In the face of these observations, it would seem that the reduction in dysmenorrhea associated with improvement in body mechanics is more than mere coincidence.

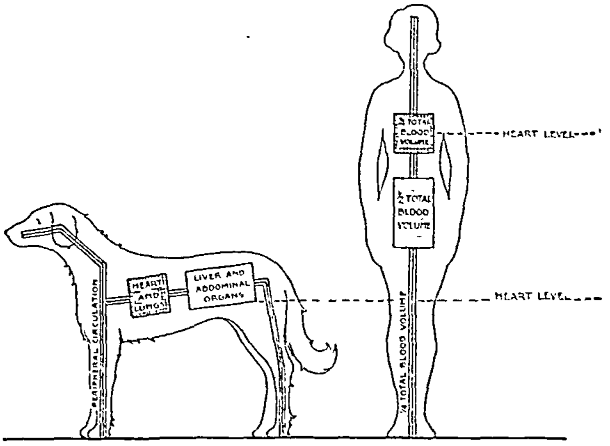

Fig. 17.—Comparison of quadruped and biped, showing distribution of blood volume: one fourth in the peripheral circulation, one fourth in the heart and lungs, and the remaining half in the portal circulation and abdominal and pelvic organs.

We hope with the completion of this study to have sufficient data to permit definite conclusions either for or against the existence of a causative relationship between menstrual discomfort and posture or more fundamental muscle tone.

ABSTRACT OF DISCUSSION

Dr George A. Kamperman, Detroit: The dysmenorrhea problem from the etiologic standpoint is one of the old unsolved problems The therapy still remains for solution. For this reason all investigation is worthy, because dysmenorrhea is a big economic problem. Many causes have been ascribed. The causes discussed by Dr. Miller are some of the causes of dysmenorrhea. Posture and muscle tone condition may be definite factors, although I do not believe that Dr. Miller intends to convey the impression that they would constitute the sole cause. All physicians are acquainted with the young woman who had dysmenorrhea in early life and who after pregnancy and the birth of a child was completely relieved of her dysmenorrhea. These patients have been seen so often that I am sure the picture is familiar. One would feel that in these cases the improvement of the dysmenorrhea could hardly be attributed to improved muscle tone or to any improvement in postural attitude. One might sincerely ask: What are the underlying causes of improvement in these cases that Dr. Miller has reported? He has studied dysmenorrhea in college girls and found that in two years' time they were greatly relieved. I believe the fact must not be forgotten that a great many girls, as they become somewhat older, oftentimes are relieved of dysmenorrhea; often that occurs just about at the age when girls go to college; when they get to the end of their teens and into the early twenties. Then dysmenorrhea often improves somewhat for some unknown reason. Dr. Miller makes a premise about which I am a little bit doubtful. He speaks of the improvement in the college girl and mentions the fact that she improves while she is undergoing the strain of college life and at a time when one might assume that neuroses would be particularly likely to cause dysmenorrhea. I am wondering how correct that premise is. It seems to me that one has to individualize a great deal in these girls. I can picture a great many girls who go to college, who for the first time in their lives are leading a regular, healthy life; girls who have been in homes where there has been no supervision, no discipline, no regularity, and who when they go to college probably for the first time in their lives are leading routine, normal lives. I can't help feeling that probably the routine life that these girls are leading may be some factor in relief of some of the dysmenorrhea.

Dr. Thaddeus L. Montgomery, Philadelphia: Either dysmenorrhea has become less frequent or physicians have abandoned efforts to discover the secret of its origin. It is held that painful menstruation is of two types: the spasmodic or essential and the congestive or acquired. The pain in the former case is usually more debilitating. The presence of a neurotic state of mind in most patients suffering with essential dysmenorrhea has been observed so universally that one familiar with a family's history and traits can usually prognosticate the occurrence of dysmenorhea in its younger generation of females. Sufficient evidence has accumulated from the reports of competent observers to indicate that the essential type of menstrual pain is frequently associated with a characteristic anatomic condition of the uterus; namely, a subdevelopment which may or may not be accompanied by anteflexion or retroflexion. Many of the sufferers from primary dysmenorrhea display systemic evidence of endocrine disturbance. Factors that act as a stimulus to endocrine development, e. g., marriage and pregnancy, frequently cure the disease. The congestive type of dysmenorrhea is a disturbance clearly secondary to such conditions as pathologic retroversion, fibroids of the uterus, pelvic inflammatory disease, and tumor of the ovary. It is generally conceded that the diagnosis of the cause in the individual patient is an intricate problem requiring searching study of both history and anatomic conditions. Can these rather positive points be alined with the studies presented by Dr. Miller? At the onset one misses the complete and detailed study of the individual case. The nature of the material studied makes such an examination difficult to a prohibitive point. Nevertheless, the absence of certain details of examination, the impossibility therefore of ruling out other influential factors, makes it impossible to accept unreservedly the importance of posture and muscle tone.

Judging from Dr. Miller's explanation of the effect of muscle tone on pelvic circulation, one would expect greater improvement in the congestive group. Measures designed to improve the mental and physical hygiene of young women should be furthered by the medical profession. Such measures impress girls with the attractiveness of vigorous young womanhood and promote a healthier attitude of mind toward bodily functions.

Dr. Emil Novak, Baltimore: It is probable that in the aggregate the amount of disability and pain produced by so-called primary dysmenorrhea is greater than that produced by any other type of pelvic lesion, and yet the study of the problem has been much neglected. I am willing to accept the view advanced by Dr. Miller that the improvement of the muscle tone in these cases and the improvement in dysmenorrhea are more or less parallel; in other words, that the muscle tone may be taken as a sort of index of the patient's menstrual pain response. On the other hand, I would be inclined to question the view that the muscle atony is the direct cause of the dysmenorrhea, for the reason that the factor of muscle tone is only one of many constitutional factors that may be concerned. Women with faulty posture and poor muscle tone are, generally speaking, women who are constitutionally deficient, as in the case of thin, anemic and asthenic girls, in whom primary dysmenorrhea is very common. I have repeatedly seen cases of severe dysmenorrhea improved or cured without any local treatment whatever, simply by improving the patient's general condition through measures of general hygiene, such as fresh air, exercise and the avoidance of overwork and worry. Normally, women suffer no pain at menstruation, although some may have a slight sensation of heaviness in the lower part of the abdomen. But if the nervous system is made hypersensitive and the threshold of pain lowered, a mere discomfort can be readily magnified into an actual pain. An analogy is seen in the mechanism of pain through toxic causes. A woman who is well can move around in bed with no pain, but if she is suffering with a severe tonsillitis, for example, with a high fever and much toxemia, every move in bed is associated with severe pain. I would hesitate somewhat in accepting Dr. Miller's statement that parous women frequently suffer with dysmenorrhea because of poor muscle tone.

Dr. J. C. Litzenberg, Minneapolis: I once wrote a paper on dysmenorrhea, touching only one phase of painful menstruation; namely, the spasmodic type. That was a paper on the use of the antispasmodics in dysmenorrhea. I found that benzyl benzoate or other drugs of the benzyl ester group would relieve dysmenorrhea of the spastic type, which is a very small proportion of the dysmenorrheas. I found to my surprise, however, that more young women were relieved by physical exercise than by antispasmodics. For the purposes of my investigation I selected a type of highly intelligent women; namely, university girls, the nurses in the university hospital, and in two affiliated hospitals. My attention was attracted to the fact, when I went to the directress of physical education for women at the University of Minnesota, that when she got out her list of young women who had dysmenorrhea in their original histories when they entered the university there were only a few women who still had severe dysmenorrhea requiring treatment, after only a few months of gymnasium work. She was convinced that the physical exercise which the freshman girls were required to take was a factor in the small number of women who still had dysmenorrhea. I found the same thing when I went to the University Hospital. The superintendent of nurses found from her records that the girls who reported that they had dysmenorrhea on entrance had been cured by the work, or at least did not have dysmenorrhea sufficient to require absence from duty. The same thing happened in all the other training schools. I learned from my investigation of the use of antispasmodics that the antispasmodic will spectacularly cure the spastic type of dysmenorrhea; but that is a small part of the group. Ever since then my first prescription for a woman with dysmenorrhea is physical exercise. When women bring their daughters to me for dysmenorrhea, I take the thorough history which Dr. Montgomery has mentioned and have a complete general physical examination, in addition to the gynecologic, made. It is most important to determine the type of dysmenorrhea if possible. Before giving any medication I prescribe certain types of physical exercise.

Dr. Norman F. Miller, Iowa City: I was interested in what Dr. Litzenberg said about his patients getting well. We have a group who are majoring in physical education, and we have succeeded in getting many of these with dysmenorrhea to take physical exercise at the time of their menstrual periods and, surprisingly enough, many of them have been relieved of their discomfort. I was also of the opinion that the parous women did not have dysmenorrhea until I studied a group of 200 cases. The individual who is relieved of her dysmenorrhea following confinement is often the type who had a small anteflexed uterus originally, associated with other evidence of underdevelopment. If this presentation has stimulated the interest of physicians in dysmenorrhea, it has accomplished its purpose. I think that one thing will have to be granted: that physicians are not particularly successful in the treatment of dysmenorrhea. I am convinced that those interested in physical education can do more for dysmenorrhea than we can.

A SIGN DIFFERENTIATING ABDOMINAL PAIN OF PARIETAL FROM INTRA-ABDOMINAL ORIGIN

A. I. RUBENSTONE, M.D.
Attending Physician, Mount Sinai Hospital; Instructor in Medicine, Jefferson Medical College
PHILADELPHIA

Acute or chronic abdominal pain and tenderness of referred origin, from spinal or sacro-iliac strain, often so closely simulates that due to intra-abdominal disorder that the differentiation taxes the skill of the diagnostician.

Orthopedists have for years called attention to this association of abdominal pain arising reflexly from spinal and sacro-iliac lesions.

A thorough investigation of the subject by Carnett[1] in the past few years has not only accentuated this knowledge but definitely shown the relationship between certain types of abdominal pain and tenderness, clearly the result of skin hyperesthesia, due to nerve transmission from the abdominal parietes, explaining many operative failures in correcting abdominal pain of long standing. He has also devised several important tests that are helpful in differentiating abdominal pain reflexly of parietal origin.

Recently a helpful test devised by Wachs, of vaginal palpation for sacro-iliac strain, has been added to the list.

Two years ago, during the course of an examination of a patient with acute right lower abdominal pain and tenderness, I observed, when the patient was placed on her right side, that pain and tenderness entirely disappeared on palpation and that she was markedly tender over the right lumbosacral and sacro-iliac joints. The abdominal pain, however, returned when the patient was again placed on her back and markedly aggravated when lying on her left side. Strapping the sacro-iliac joints with large strips of adhesive plaster brought immediate relief from the abdominal pain. The patient was afebrile. The physical examination otherwise revealed no gross abnormalities. Functionally, aside from moderate intestinal stasis, the history was entirely negative. Blood studies revealed no leukocytosis nor any other cytologic, serologic or chemical abnormalities. Gynecologic and kidney function tests were normal. Gastro-intestinal studies, including a roentgenogram, revealed no abnormalities. Roentgen examination of the two sacro-iliac regions and the lower part of the spine revealed a mild bilateral arthritis, more pronounced on the right than on the left side. Following marked relief from pain, after strapping, a well fitting sacro-abdominal support continued to give the patient complete comfort without recurrence of the pain.

All patients admitted to my service at the Mount Sinai Hospital and at my office, complaining of lower abdominal pain, were subjected to the test and invariably it has proved reliable in differentiating pain of intra-abdominal origin from that due to parietal lesions.

It was consistently found that abdominal pain of intra-abdominal origin is not relieved when the patient is turned on one side or the other, but even markedly aggravated. In patients observed with abdominal pain due to bilateral sacro-iliac strain, relief from pain was always obtained on the side on which the patient rested. When patients suffered not only from sacro-iliac strain but also from intra-abdominal conditions there was no relief from pain on change of posture.

The technic of obtaining the sign is simple. The test is performed as follows: With the patient lying on her back, palpation of the abdomen establishes the area of maximum pain and tenderness. Without taking the palpating fingers from this area, the examiner turns the patient on the same side so that the pelvis rests on the iliac crest (it is well not to have the mattress too soft). Even deeper palpation over the same area will elicit little or no discomfort if the pain is referred from the sacro-iliac or lumbosacral joints of the same side. Turning the patient on the opposite side will usually aggravate the pain. The patient is then placed on the abdomen and the sacro-iliac joints are palpated. Invariably tenderness is elicited, sometimes over the entire area of the joints or a portion of it. Sometimes the tender point is sharply localized so that one must carefully and patiently press over the entire area of the joints in order to establish the local tenderness. It is often necessary to use very firm pressure to elicit this tenderness. It is sometimes spotlike.

An explanation of the relief from abdominal tenderness and pain, when the patient lies on the same side, is probably due to temporary immobilization of the joints affected, with lessened skin hyperesthesia due to reflex nerve transmission.

It is noteworthy that many of these patients have no subjective complaints of parietal pain, because of the absence of marked inflammatory phenomena in the joints affected.

In my many observations in the past two years it has been interesting to note how frequently abdominal pain of referred origin from the parietes is encountered without any subjective symptoms referable to the joints affected.

REPORT OF CASES

L. B., a woman, aged 31, was admitted to the Mount Sinai Hospital, July 6, 1929, complaining of pain in the left side of the abdomen, radiating down to the inguinal region, accompanied by occasional vomiting, of chronic and recurrent standing, for which an appendectomy had been previously performed, without relief.

On physical examination the pain and tenderness over the left side of the abdomen was relieved as long as the patient rested on the left iliac crest. When the left sacro-iliac joint and the hips were palpated, the entire area was extremely tender, although the patient did not subjectively complain of pain in this region.

Gynecologic and urologic studies, including pyelography, were entirely negative. Gastro-intestinal studies, including roentgenography, were entirely negative.

Orthopedic and roentgen examination confirmed the diagnosis of a lumbosacral strain and intercostal neuralgia due to arthritis, and relief was obtained by measures directed toward overcoming the parietal lesions.

A second instance in which a slight intra-abdominal abnormality was credited with abdominal pain and tenderness is as follows:

A. W., a woman, aged 30, was admitted to Mount Sinai Hospital, Dec. 2, 1929, complaining of pain in the right lower quadrant, of several years' duration, at times markedly aggravated and incapacitating the patient.

---

[1] Carnett, J. B.: Ann. Surg. **85**: 509 (April) 1927, Am. J. M. Sc. **174**: 579 (Nov.), 833 (Dec.) 1927.

On previous study at Mount Sinai Hospital, a right ureteral kink was blamed for her symptom complex, which also included indefinite gastro-intestinal symptoms, such as belching, pyrosis and headache. During the previous two years, treatment directed toward the alleviation of the ureteral kink brought no relief from the abdominal pain.

On her present readmission I found that the right lower abdominal pain was immediately relieved when she was placed on her right side and predicted, before the parietes were examined, that she probably had a lumbosacral or sacro-iliac strain on the same side. This proved to be so, to a marked degree. When a cast was applied, the patient obtained complete relief from her symptom complex for the first time in several years and has had no complaint since.

COMMENT

The ureteral kink in this patient, if present, is not responsible for her former symptoms. It might have been artificially produced during the pyelographic studies, as was pointed out by Thompson and Bumpus.[2]

It is needless to emphasize that, in patients with abdominal pain, intra-abdominal lesions should be ruled out before the parietal origin of the pain is definitely established as the only cause; it is hoped that this sign will be helpful in such differentiation.

ATYPICALLY SITUATED SARCOMA OF THE CONJUNCTIVA

REPORT OF A CASE *

HOWARD McILVAIN MORTON, M.D.
MINNEAPOLIS

Melanotic sarcoma of the conjunctiva, since the first case reported by Baumgarten[1] in 1852, has been described in the literature of ophthalmology and cannot now be considered a clinical rarity, although Roemer[2] states that "sarcoma of the conjunctiva is a very rare disease." However, the clinical expressions in the case to be reported are somewhat different from those usually found in this form of malignancy attacking the conjunctiva. For this reason, as well as to add another case of conjunctival sarcoma to the limited literature on this disease, the following case is presented.

REPORT OF CASE

History and Description.—W. E. B., a white man, aged 37, married, and with a healthy family, presented himself for examination, Feb. 17, 1930, because of a growth on the eyeball of three years' duration. The patient was 5 feet 9 inches (175 cm.) in height, weighed 160 pounds (72.6 Kg.), and was in normal general health. Cardiovascular conditions were normal; blood tests showed no constitutional disease. Several brothers and sisters, as well as the parents, were in normal health. There was no family history bearing on the condition—it was negative in all regards. The patient had never been sick. He was a healthy and strong farmer, and of a high degree of intelligence. He had reddish hair and a florid complexion. There was no pigmentation on the body. There was also no pigmentation (excepting the growth) either on the conjunctiva or on the lids. The fundi were normal and had a normal degree of pigmentation. There was no accentuation of the choroidal ring in either eye.

The patient gave a negative history, except that about fifteen years before he had had some metal filings blow into his right eye. This incident was evidently not related to the present condition, since the injury was nothing more than a slight irritation that passed away in a few days, the material being removed immediately and without trouble. This occurred about 1915, and there were no further disturbances of the eye until twelve years afterward, or about three years before I saw the patient. At that time, while threshing, he noticed that his right eye was sensitive to the dust, and that it bothered him more than did the left. He was not sure that he had gotten anything in the eye. Thus, aside from this vague and indefinite observation, the history was negative.

About three years before the patient came for examination he observed a small brown spot in the conjunctiva of the right eye, and about 4 or 5 mm. from the edge of the cornea. This remained unchanged in character until about eighteen months before. Since that time there had been a rapid advance in the outlines of the spot, until at present there was a large brown, or black, growth situated in the conjunctiva, to the outer side of the cornea. It apparently consisted of two connected portions, the one medially situated being blackish brown and about 7 mm. long and 3 mm. wide. The other segment, nearer the canthus, was an almost globular-looking mass, about 7 or 8 mm. in diameter. The surface of the tumor was smooth but with nodulations that were not small but consisted rather of three or four lumpy areas. Its thickness varied from 2 to 6 mm., there being an almost conical apex at its thickest part. The growth was freely movable in the conjunctiva over the sclera and was apparently confined to the conjunctiva. The nearest approach to the corneal limbus (fig. 1) was 5 or 6 mm.; there was no pigmentation elsewhere on the eyeball. While there seemed to be no pigmentation involvement about the limbus, there was a distinct, clear, flat, nonpigmented and colloid-like elevation between the edge of the tumor and the limbus of the cornea. The growth was gradually thicker and wider as it approached the outer canthus, and was also less freely movable about these areas. It had zones of vascular fringe passing out into the conjunctiva. The anterior ciliary vessels at the inner canthus were much engorged and were distinctly bluish. There was much new vessel formation, which radiated upward and downward, but this did not extend beyond the beginning of the tumor. There were no noticeable vessels on the tumor itself, except at its thicker (base) attachment to the tissues at the outer canthus. It spread out thicker at the base and narrowed almost to a blunt point in the direction of the cornea.

The ocular excursions were normal and the size of the pupils was normal, although there was a little irregularity of the left pupil (the noninvolved eye) at about 4 o'clock. Pupillary reactions, both direct and consensual, were normal. The color of the irises was gray, and the pupil was slightly miotic. The cornea in each eye was slightly below the average in diameter, being about 11 mm. In the iris of the right eye were a few brownish radiations of pigment, and in the iris of the left eye were considerable irregular pigment deposits, between 3 and 6 o'clock. Vision in the right eye was 6/6; in the left, 6/5. The growth was brownish, or almost entirely black, and, as already stated, contained a few nodular elevations and depressions. The patient did not complain of subjective symptoms, except that the eyes tired on reading. He had never worn glasses and had never had pain or attacks of inflammation in the eyes. There was no family history of tumor growth. The ophthalmoscope showed clear media and normal disks, with normal vessels, and, while the fundi were somewhat rough, there were no definite lesions. The conditions in the left eye were the same. The visual fields were normal in their peripheral extent, as were the central fields.

Microscopic Report.—The specimen was examined by Dr. E. T. Bell, professor of pathology at the University of Minnesota, who reported as follows: Microscopic sections of the tumor showed closely packed cells with an irregular alveolar arrangement. The cytoplasm was abundant and no distinct cell boundaries were visible. Many of the cells contained granules of melanin pigment. Numerous mitoses were seen. The microscopic structure afforded convincing evidence that the tumor was a melanosarcoma (fig. 2).

TREATMENT AND AFTER-TREATMENT

In the light of general experience, perhaps quite well represented in the report of Verhoeff and Loring[3] that 80 per cent of epibulbar sarcomas recur, both treatment and after-treatment in these cases seems to be almost, or entirely, futile. These writers express the opinion that the growth is highly malignant and with a tendency to recur and to form metastasis—the almost universal experience. Roemer, however, states that metastases from sarcoma of the conjunctiva are infrequent. In an accumulated series of fifty-three cases of epibulbar conjunctival sarcoma (Verhoeff and Loring), thirty-six recurred, and metastasis occurred in eight. It is to be assumed that there were many more recurrences and metastases, since some of the subsequent histories of this total number were not available. It has been my experience that metastasis from intra-ocular sarcoma occurs within two or three years, but statistics show that recurrence may not take place and metastasis may not appear for many years—ten or more. Therefore, opinion as to the final result must be withheld for a long time. The experience of all, however, is not so unfavorable. F. E. Burch[4] states:

> I have seen three of these cases in recent years and all have behaved well after removal. The first was removed elsewhere, had a recurrence, and we treated it entirely with x-ray therapy. There has been no recurrence after seven years. The second was treated by fulguration after a biopsy. The third was treated by diathermy fulguration extending well onto the cornea and rather deeply into the sclera. Neither of these fulguration treated cases have recurred. None of my three cases were nearly as large as yours, nor so loosely attached to the sclera and conjunctiva as this one. All were diagnosed as melanotic epitheliomas (one was sarcoma). All have retained the eyeball to date, and so far as I know, none have recurred. In the last two cases they were followed up with radium locally, which, I think, is the most valuable aid in prevention of recurrence.

Recurrence being so imminent and metastasis so frequent, it would appear that the generally expressed opinion that enucleation be immediately carried out is the proper course. However, such haste as a routine procedure may not be justified. The question of procedure in these cases must be viewed from several standpoints, and from each it appears somewhat different. In the large general clinics, such methods of procedure may be conveniently carried out. In private practice, one must admit that there may be cause for hesitation as to the course to pursue. We recognize that both epitheliomas and sarcomas are almost sure to recur or to form metastases. The problem is the more complicated since often the eye affected has normal visual acuity—vision may even be better than in the eye not involved. It is difficult to persuade the patient that a good eye should be removed, and since the surgeon knows that even if it is removed the final effect, through recurrence and eventual metastasis, is usually tragic, there appears to be justifiable hesitation as regards enucleation. It is true that such arguments would not be sound if they eliminated, to a reasonable percentage, the danger of recurrence, but the testimony is rather otherwise. It therefore seems at least justifiable to remove the growth to the fullest possible extent, and in some cases this may be accomplished. The problem is even more complicated in view of the fact that Fuchs[5] and others have pointed out that there is a disposition toward the formation and recurrence of epibulbar tumors at the limbus, and furthermore that disposition to tumor metastasis may reach farther back into the general system—a tendency rendering recurrence still more probable. On the other hand, it is possible that recurrence may be retarded, or possibly avoided, by such forms of therapeusis as roentgen rays and fulguration (Burch). Weeks[6] believes that small pigment spots about the limbus should always be regarded with suspicion and removed the moment they begin to enlarge.

In the case reported here the tumor was readily removed, and, apparently, without leaving involved areas. Of course, this assumption can be clearly and definitely indicated only by the microscopic examination. The large uncovered area left was thoroughly curetted with the sharp edge of a cataract knife, all episcleral tissue being removed, and the raw surface was then completely covered by large Kuhnt flaps. The wound healed rapidly and looked well at the end of four or five days, when the patient returned home, to report later.

COMMENT

Sarcoma attacks the interior of the eye much more frequently than it does the exterior, and in the latter case almost always appears at the limbus as an epibulbar growth. These growths are usually pigmented, although nonpigmented sarcomas occur (one to five, according to Parsons[7]).

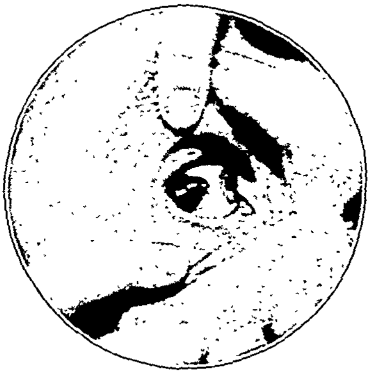

Fig. 1.—Appearance of eyeball, showing conjunctival growth.

Melanotic sarcomas develop in locations in which pigment is commonly present. In the case reported, the growth was separated from the limbus by at least 5 or 6 mm. Numerous cases have been reported of multiple sarcoma at the limbus, which, when removed, recurred at another situation in the same eye. The base is nearly always small, even when the growth is large, and many growths lie over the cornea without being adherent to it, which Parsons believes is a distinguishing sign from epithelioma. The deep part of the growth is usually about an area supplied by the anterior ciliary vessels, as was true in my case. When epibulbar sarcoma occurs at the limbus, the corneal stroma is usually not invaded, or, if so, is invaded mostly in the superficial areas alone. In a case reported by Wadsworth and Verhoeff,[8] the anterior third of the cornea was infiltrated, and in Sgrosso's[9] case the entire cornea was involved during the latter stages. Adamück[10] reports a sarcoma of the bulbus that became as large as an orange. A small tumor may, in rare cases, be accompanied by widespread pigmentation of the conjunctiva.[11] I have seen two other cases of melanosarcoma of the eyeball which appeared as small growths at the iris margin. Both growths were removed without difficulty, and, in both, metastasis to the liver occurred and the patients died within three years after the time of operation. These cases have never before been reported in the literature.

Sarcoma in other parts of the conjunctiva than the limbus is rare. A case involving the upper fornix has been reported by Griffith, and another at the inner angle of the socket of an enucleated eye has been reported by Gorecki. Cases of sarcoma of the palpebral conjunctiva have been reported by Mittendorf, Ewetski and Feilchenfeld. According to Fuchs, sarcoma, in contrast to epithelioma, grows more in height than in breadth and is usually attached by a small and slender base or pedicle. Sarcoma of the conjunctiva is almost always pigmented, differing in this respect from epithelioma. The sarcoma usually develops from areas in which pigment is normally present and for this reason manifests a tendency to appear at the limbus, where pigment, even under physiologic conditions, frequently occurs. Not infrequently at this area pigment moles are found, somewhat flat in character, with a structure somewhat similar to that of the soft nevi of the skin, and out of these sarcoma frequently develops. Both types, either the pigmented or the nonpigmented, possess a high potential capacity for malignant development. These pigmented areas are flat and consist of groups of large cells of endothelial type. The pigment is found both within and without the cells, and the connective tissue surrounding it may also be pigmented. The epithelium over the spot also frequently contains pigment, and when this starts to proliferate it may form an intensely malignant melanotic growth. There is difference of opinion as to the origin of the growths just described (nevi), Recklinghausen believing that they come from the epithelial cells of the lymph vessels, and Unna that they come from the surface epithelium, while Ribbert thinks that they arise from the chromatophores. Nevi situated at the corneal limbus may remain for many years without change but, when they start to grow, may develop rapidly into sarcoma. Roemer states that both epitheliomas and sarcomas readily recur but when situated in the conjunctiva rarely penetrate the eye. Some believe that, when they are so situated, metastasis rarely occurs. In intra-ocular sarcoma this is quite different, since early metastasis is much to be feared. The epithelioma may contain pigment, and since a sarcoma may also be a leukosarcoma, histologic differentiation may be difficult, as both forms of tumor have an alveolar structure; but usually sarcoma of the conjunctiva contains pigment, while the epithelioma does not. The epithelioma is usually nonpigmented and is flatter than the epibulbar sarcoma.

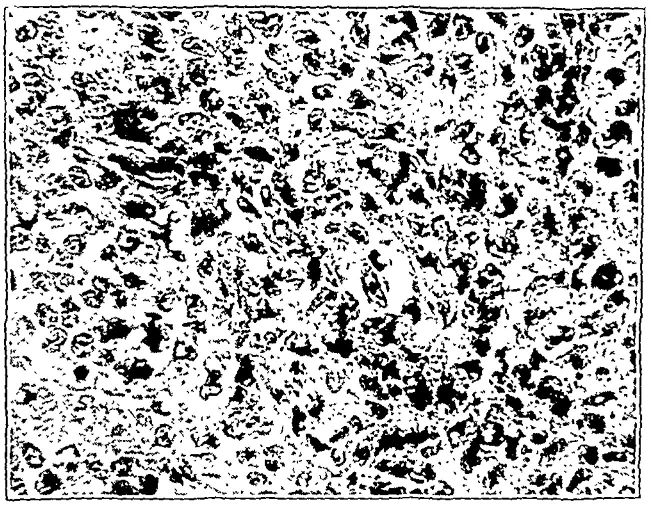

Fig. 2.—Microscopic structure of growth indicating that it was a melanosarcoma.

According to Parsons, microscopic study of sarcoma of the limbus shows few peculiarities; the growths consist of round or spindle-cell growths, varying in the different cases and generally arranged in bundles. According to Wadsworth and Verhoeff, multinuclear cells also may occur, and Parsons believes that these are not true giant cells as found in myeloid sarcoma but merely the evidence of rapid cell division. Commonly, they have an alveolar arrangement, having rings and columns of cells enclosed in a fibrous tissue framework. This peculiarity of structure caused Panas[12] to doubt the frequency of sarcoma at the limbus. Panas believed that tumors at this point should be regarded as mixed epithelioma and sarcoma, and as nonmalignant in character. Parsons strongly protests against the acceptance of this idea, asserting that the idea of the simultaneous occurrence of carcinoma and sarcoma is not to be accepted. Different views are held as to the origin of melanotic sarcoma—as to whether it is developed by the tissue cells or from hemoglobin. Penetration of the globe from conjunctival sarcomas is rare but does occur, the extension of the growth passing along the perforating anterior ciliary vessels.

1111 Nicollet Avenue.

TUMORS OF THE EYE AND ADNEXA *

E. H. CARY, M.D.
DALLAS, TEXAS

The medical literature of recent years abounds in minute descriptions of tumors in and around the eye. I have thought, however, that my own observations and results might be of some value to my younger confrères whose experiences await them.

Most intra-ocular tumors are malignant. Tumors occurring near the eye in the orbit are more frequently benign; tumors occurring on the eye itself are often epitheliomas with a tendency to metastasize.

I shall refrain from the use of detailed reports from the laboratory. Photomicrographs and minute laboratory descriptions have filled many pages of medical literature, where a statement of clinical observations would have sufficed. As the subject matter of this paper involves several types of malignant and benign growths, I will utilize the conventional classification and try to bring to attention the points that were of clinical interest.

Collins and Mayou[1] subdivide neoplasms into (1) teleplasms; (2) metastatic growths, and (3) cysts. Teleplasms are subdivided into three classes: teleplasms from mesoblasts, teleplasms derived from neural epiblasts, and teleplasms arising in parts, derived from mesoblasts.

---

TELEPLASMS FROM MESOBLASTS

One of the earliest intra-ocular complications occurring in my private practice was apparently a glioma in each of a child's eyes, and, one would have supposed, derived from neural epiblasts:

Case 1.—The child was 10 months old in the fall of 1902, when he was brought to me. The physician sent the child on account of the yellow reflex in each of the pupils, and supposed blindness. The mother stated that the child had been ill with pneumonia. On examination, it was thought that each eye was in tension. The anterior chambers were shallow. The pupils were slightly increased in size. The irides were not adherent—the golden reflex was seen through the lens, and it was my judgment at the time that it was not pseudoglioma in spite of the possibility of a metastatic choroiditis having occurred from pneumonia.

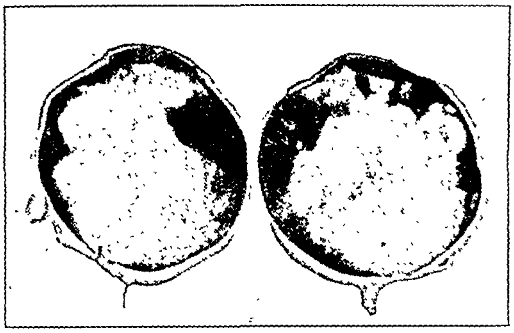

Fig. 1.—Neuro-epithelioma in a child, aged 18 months: optic nerve invaded; posterior two thirds or more of eye filled.

Sympathizing with the mother, who objected to both eyes being enucleated, I treated the child with available x-rays for approximately fifteen minutes in each eye, on alternate days, for a period of six weeks. The x-rays available were made by the old static machine then in use. Eight years later I removed the crystalline lenses of the child, as they were calcareous. Afterward I split the posterior capsule, as well as a dense membrane that lay in front of the detached retina, and secured for the child some vision from a portion of the eye corresponding to the retina, which was intact.

In those days there were no tonometers and roentgenology was crude. I had seen gliomas in hospital service, and I felt certain of my diagnosis; but the fact that the child did not die contributed to my education. I was left in doubt as to the diagnosis and yet, although a quarter of a century has passed, I can recall all the reasons for my conclusions when the diagnosis was made.

I am reminded of this case and recall it here. Since the literature indicates that the x-rays frequently destroy a new growth of sarcomatous nature and since the later reference to the paper by Parker and Stokes[2] suggests that gliomas are at times sarcomatous, I feel that this patient should probably be classified as having had tumors derived from the mesoblast, these cells being possibly more susceptible to the influence of this long repeated dosage of mild x-rays.

Pfahler[3] describes a series of twenty-six cases of sarcoma treated by him with unique results. He states that in three of his cases of intra-ocular sarcoma the disease had been arrested from three months to eighteen years. He states that in fourteen cases of primary retrobulbar sarcoma he failed in two cases whereas in nine cases there was freedom from symptoms from one to nine years. He concludes that there has been improvement from irradiation, but the use of radium has ultimately failed in recurring cases of sarcoma of the orbit. He also states that the x-rays have been successful in the majority of cases of primary sarcoma of the orbit and should be the method of choice in treatment. Irradiation does no harm to the normal tissues, and he thinks a biopsy for diagnostic purposes does not seem justified.

In the light of the study of the pathologic material from Parker's clinic made by Warthin, all of the so-called gliomas were, in fact, round cell sarcomas. Six of the neoplasms had their origin in the choroid and two in the retina. Two were undetermined. This statement, based on an excellent study of the material, is at variance with what we have all been taught and believed about glioma seen in little children.

I have wondered many times whether the x-rays had not succeeded in destroying the tender embryonic cells, sarcomatous in fact, which left the child with the kind of eyes I found to operate on many years later.

According to Fuchs, malignant neoplasm developing in the eyeball will have to be regarded as a glioma in a child and a sarcoma in an adult. The fact remains that the tumor is exceedingly malignant, regardless of the particular tissue in which it arises. Parker calls attention to the fact that a majority of writers agree that "a proliferation of glial tissue cannot have a high degree of malignancy observed in intra-ocular neoplasm, and that a glioma of the retina has nothing in common with a glioma of the central nervous system." In the light of this pathologic study a grave doubt is raised as to the correctness of the term "glioma of the retina" as all inclusive.

TELEPLASMS DERIVED FROM NEURAL EPIBLASTS

The cases presented here serve to emphasize to the general practitioner that he should know more about intra-ocular growths. It is hardly conceivable that parents would delay bringing their child to an ophthalmologist if practitioners were more observant and more promptly interpreted the meaning of the golden reflex, sometimes called an "amaurotic cat's eye."

I have pathologic material from four children which seems undoubtedly to be derived from neural epiblasts that can be classified as "neuro-epithelioma of the retina," each of these far advanced. Three of them had grossly invaded the postocular structures; in one, it was necessary to section the optic nerve, when I was able to demonstrate the outgrowth of the cells. Case 2 was seen recently:

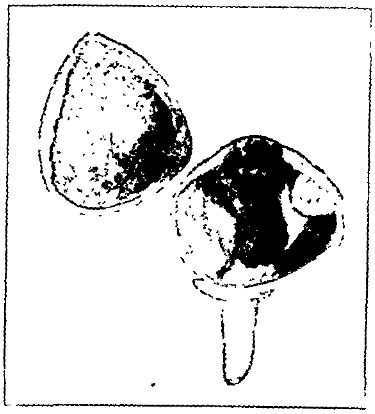

Fig. 4 —Sarcoma near ciliary body.

Case 2.—I removed the left eye from a child, 18 months old. The tumor almost filled the posterior two thirds of the eye. The family observed the golden reflex in this eye from the time the child was 8 months old, the child being 18 months old when it was brought to my office. It was left to the surgeon in a nearby city, who made a diagnosis of cataract and sent the child to me for advice.

[3] Pfahler, G. E.: Roentgenotherapy in Sarcoma of the Orbit, J. A. M. A. 84: 87 (Jan. 10) 1925.

The three other cases of this type, one in a baby 14 months old, were described by the parents as beginning with a cloud coming over the eye for three months before they sought advice. A well developed glioma was recognized in the child aged 14 months, and the eye was removed, Feb. 14, 1921. Dec. 19, 1921, the tumor had returned; this was all exenterated and radium was used. The baby died, March 20, 1922.

Case 3.—A child, aged 19 months, was seen, January 24, 1922. The mother thought she had observed that the left eye was smaller at birth. Four months before, a golden reflex was observed. The eye grew larger without apparent discomfort to the infant. Within the last two weeks the eye had been growing rapidly, and at the time of examination there was extreme exophthalmos. January 25, the orbit was exenterated and 50 mg. of radium was left in for twelve hours. The patient apparently did very well.

The pathologic report was glioma of the retina with invasion of the orbital tissue. The specimen consisted of the eyeball, together with the conjunctival sac of the orbit. The eyeball was elongated posteriorly, where it was irregular and nodular, by a tumor mass that protruded, forming a mass 13 by 1 and 8 by 1 cm. This mass was covered by smooth intact membrane. The tumor mass occupied almost the entire globe and, in addition, invaded the surrounding tissues. The mass within the eyeball was largely necrotic. The child returned in six months and radium was used again. The condition was hopeless, and the child died soon afterward.

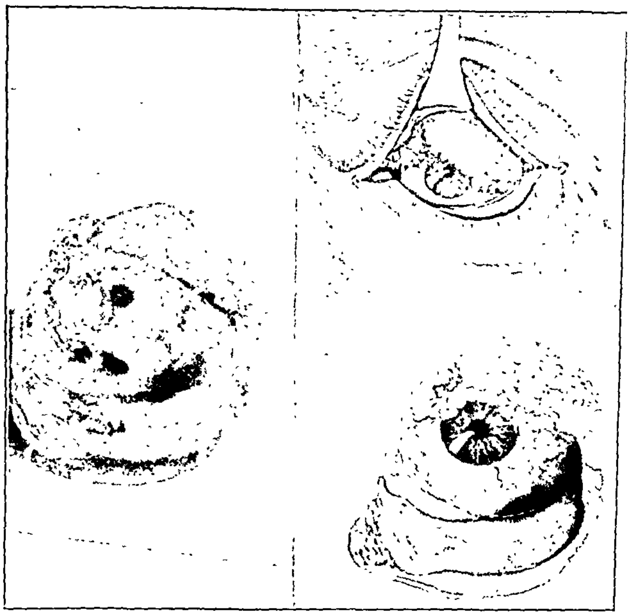

Fig. 8.—Extensive papillomas in patient, aged 82: drawing before removal; photograph of specimen afterward.

In the differential diagnosis of glioma from the pseudogliomatous conditions, Butler[4] points out the value of the slit lamp examination. He asserts that one will find cells circulating in the anterior chamber and that the retrolental space will be filled with cells, all of which would indicate pseudoglioma or an inflammatory process, whereas an absence of cells would be observed in case of tumor. In none of these cases would the use of the slit lamp be essential, for they were all far advanced; but it is conceivable that the slit lamp study would be of great value, as has been pointed out by Butler.

TELEPLASMS ARISING IN PARTS, DERIVED FROM MESOBLASTS

In adults, these growths are seen so near the optic disks that it would seem easy to assume that the growth is connected with the nerve structure; but they are found growing from the choroid and, located as they are, it is impossible to utilize transillumination successfully. There are two types of these tumors, the pigmented and the nonpigmented.

In the light of some recent literature, the origin of melanotic or pigmented tumors of the eye is difficult to determine. Neoplasms which cannot be classified as rapidly growing tumors are made up of young, or embryonic, cells that have not developed distinctive characteristics. The cytoplasm in the cell is more abundant, and the characteristic cell type develops when the tumors are slow growing, while rapidly growing tumors have cells with large or multiple nuclei with little cytoplasm. Melanin[5] is produced by mature epithelial cells highly differentiated. Energy is spent in this production; hence tumors grow more slowly than when nonpigmented, such as the unpigmented tumor of the choroid.

I have quoted the observations of Warthin, who reclassified gliomas as round cell sarcomas, confusing our conception of the origin of gliomas. Now, in a reverse manner, we are called on to reclassify and revamp our views of the melanosarcomas; for instance, one is taught that the choroidal coat of the eye comes from the mesoderm; that the formation of pigment is a product of the epithelium which is from the ectoderm, and therefore that the melanin which is reproduced originates from the epithelium itself. Hence the modern term melano-epitheliomas.

The foregoing, I think, states in simple language the result of the study of this subject, which seems now to be confusing in an interpretation of the origin of the cells that have become malignant in the locality under discussion.

It has been found in the great eye clinics[6] that sarcoma of the choroidal coat is comparatively rare. In point of frequency it occurs once in approximately 2,500 ophthalmic cases. There are definitely four stages in the development of sarcoma of the choroid:

1. The tumor grows without apparent irritation.
2. Secondary glaucoma is recognized by increased tension.
3. There is continual growth of the tumor, and rupture of the globe.
4. Intrabulbar growth becomes extrabulbar and there is an increased opportunity for metastasis.

As an aid to early diagnosis I value highly the use of transillumination. A shadow shutting out the red reflex in the pupil may, of course, mean a large hemorrhage, but occurring in connection with other circumstances it is most helpful in concluding the diagnosis.

If the tumor should arise in the ciliary body or near it in the choroid, it may be difficult to see, although easy to transilluminate.

[6] Keiper, G. F.: Melanotic Sarcoma of the Choroid Coat of the Eyeball: Report of a Case with Apparent Secondary Involvement of the Retina, Ann. Ophth. 22: 445, 1913.

One of the first tumors of the choroid I saw in private practice was in 1903 in a woman:

Case 4.—Mrs. C., who had been under observation for some time by a confrère, came to me with secondary glaucoma. I could see into her eye, and made a diagnosis of sarcoma. It was quite large and located near the equator. I removed her eye and our pathologist, in cross-sectioning, managed to cut through the retinal vein. He reported that he found a cell within the vein. I kept in touch with the patient, expecting an early metastasis. When five years had passed, I doubted the pathologist's observation. Nine years after the eye had been removed, a sarcoma developed in the patient's left lung, which grew rapidly and from which she died. Incidentally it was her left eye and left lung that were affected. The slide was at the college for some time and although it was misplaced I found the specimen with the tumor fairly preserved and had another section made through the nerve, with the pathologic report that the vein was filled with pigment.

Case 5.—In 1912 a man, aged 23, came to me complaining of the field of vision of his right eye. With an ophthalmoscopic examination, a small detachment could be found over a dark growth near the ciliary body. Although his vision was good, he was persuaded to let me take out his eye on account of the belief that he had a sarcoma growing from the ciliary body. This was done. A cross-section of this eye was used as an example of the inability of any one to make a diagnosis of a tumor in the region where this was located, unless the pupil was dilated.

For three or four sessions of the legislature, during an argument before the legislative committee, this tumor was shown, and it is interesting to say that the majority report invariably sustained our arguments. I always thought the demonstration of this tumor was the determining factor in checking the efforts of those who wished, through statutory enactment, to secure preferential legislation.

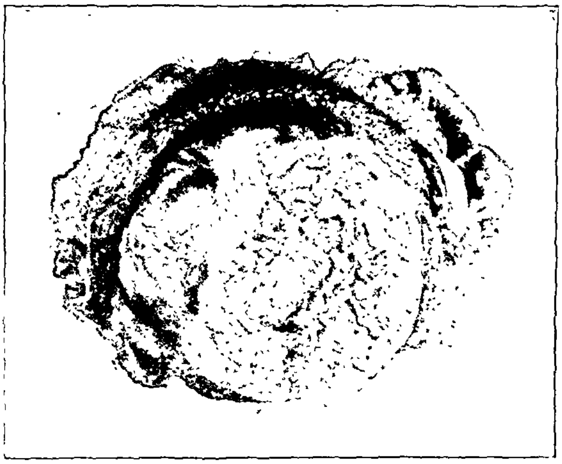

Fig. 9.—Epithelioma involving conjunctiva and lower lid.

Case 6.—Mrs. T., aged 36, seen in 1915, had noticed for some time that she was unable to see below with the left eye. A detachment was found above and what was also thought to be a tumor producing the detachment. The patient's detachment increased and secondary glaucoma was precipitated; the eye was removed and a melanosarcoma was found located in front of the equator above the horizontal meridian. The patient remains alive.

Case 7.—Mrs. C., aged 41, complained of a disturbance of vision in the right eye. The Wassermann reaction was negative. Of the eight sarcomas of choroidal origin in adults, three had one characteristic in common. Each grew from a place near the nerve head and transillumination could not be used effectively. This one I watched for some weeks. It looked at first as if I were dealing with a cyst, and this cystic appearance was round, smooth and apparently growing from the side of the nerve head itself. Transillumination showed nothing. I became convinced, however, that it was a detachment, and that it was of tumor origin. The vision was 20/200 in the affected eye and 20/17 in the left eye. The eye was removed and *the tumor was found growing from the point which* approximated the nerve head. The patient is living.

Case 8.—Mrs. C., aged 38, was examined, May 9, 1928. The Wassermann reaction was negative. There was a complete detachment of the retina. The patient had been blind three years before secondary glaucoma developed. The patient was seen two days before symptoms of glaucoma, when the tension was 10. A diagnosis was made on the basis of the history and deductive reasoning. Transillumination was of no service. The latter case was shown at one of my clinics, where a preoperative diagnosis was made. Following the removal of the eye, it was hardened over night by the injection of 10 drops of 36 per cent solution of formaldehyde, which was injected through the optic nerve. The next day the eye was cross-sectioned, the interior being thoroughly hardened by the procedure of the previous day.

The question arises, In how short a time after the injection of formaldehyde would it be feasible to cross-section an eye? I have found it most desirable to harden and cross-section macroscopically for class teaching. The older method of waiting several days rather caused one to lose interest and frequently not to observe the pathologic changes disclosed by operation.

An experiment was made on pigs' eyes, a dozen of them being injected through the optic nerve with from 8 to 10 minims (0.5 to 0.6 cc.) of solution of 36 per cent formaldehyde. These pig eyes were injected through the nerve and the nerve was tied as the needle was withdrawn. The eyes were cut at intervals of one hour, and in those in which the vitreous seemed to grow firmer and harder and in which the retina was not detached any from the procedure of cross-sectioning the eye, the vitreous was not solidified within a period that would make it practical to open the eye on the day of the operation; yet in a lapse of many hours extending to the next day, the mass does solidify and will answer every purpose, as in the demonstration in the case under discussion.

Case 9.—Mrs. R., aged 34, seen Oct. 29, 1928, had a tension in the left eye of 8 and in the right of 15. When light was brought over the nasal area, the pupillary light was lost. The retina was detached over that portion, the nasal quadrant and beyond. The patient stated that the vision in the left eye had at first gradually diminished, but later noticeably over a period of four years. The eye was removed. The diagnosis was substantiated, and the patient is living. The specimen showed choroidal tumor. The diagnosis was melanosarcoma.

Case 10.—C., a man, aged 40, seen Oct. 14, 1929, had a tension in the right eye of 34 and in the left of 18. He stated that he discovered that vision was gone in the right eye about three months before. He felt certain that his vision had been all right within the year. The general health was good. The Wassermann reaction was negative. The lid on the right side seemed to be drooping. It was impossible to use the perimeter. The pupil when two thirds dilated did not react to light. The retina was detached. The diagnosis was malignant tumor. The eye was removed, and the diagnosis confirmed. The specimen was preserved. The patient is living.

TELEPLASMS DERIVED FROM CUTICULAR EPIBLASTS

I have selected three interesting cases to consider under this classification:

Case 11.—A., a man, aged 62, had an epithelioma of the cornea, diagnosed as a pterygium. He had been operated on three times elsewhere. I removed the globe in 1907. Within twelve months the patient returned with a metastatic tumor of the neck. Further operations and treatment were of no avail, and the patient died.

Case 12.—A., a man, aged 82, seen Oct. 10, 1928, had observed a growth for a year, the size of which had increased rapidly during the past two months. The size of the growth, the age of the patient, the likelihood of its return and the inability to cover the eye with conjunctiva if the growth alone was removed determined me to remove the eye and adnexa. Besides, I believed that the growth was malignant. There was no history of cancer or tuberculosis in the family. The growth was diagnosed as epithelioma of the left eye. The postoperative diagnosis was papilloma. At operation, October 20, the globe and adnexa were removed. At biopsy it appeared nonmalignant, but the pathologist asserted that deeper sections through the tumor would probably give evidence of a malignant condition. The patient is living.

Case 13.—A negro, aged 73, with a history of an extra-ocular bulbar growth in the lower quadrant of the left eye, growing since June, 1929, was operated on by a clinical assistant in my clinic in October, 1929. Microscopic examination showed squamous cell carcinoma. The patient lived out of the city and returned in February, 1930, with a history of the growth having returned in December, 1929. The eye with the conjunctiva, except for cutaneous tissue, was completely removed by me, leaving orbital fat. The presence of skin saved closing the wound. Radium was advised.

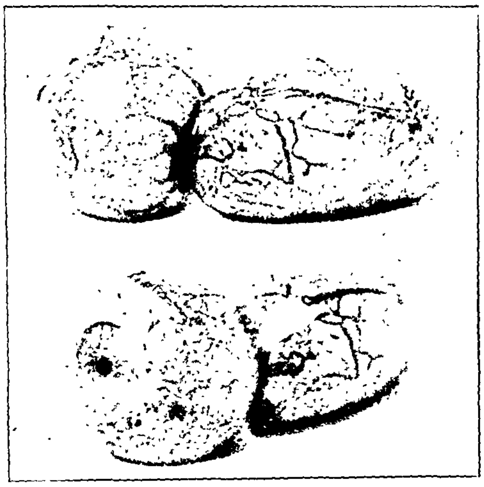

Fig. 10.—Neuroma of optic nerve.

OPTIC NERVE TUMORS

I have had two cases of optic nerve tumors, one derived from neural epiblasts and the other from mesoblasts.

Case 14.—*Neuroma of the optic nerve.* A woman, aged 21, had marked exophthalmos, the macular region being pressed forward as if purposely done with the movement of the finger; the optic nerve was white, the media were clear, and the eye was protruding but mobile in all directions.

The diagnosis was tumor of the nerve. The eye and the nerve extending to the foramen were removed. No orbital fat was observed. The pathologic report was true neuroma of the nerve. The nerve tissue was entirely dominating.

Macroscopically the glistening appearance of the loose and soft looking smooth tissue was extremely interesting, for the fibrous element was of slight moment and apparently not a factor in the production of the tumor.

Case 15.—*Fibroma of the optic nerve.* M. C., a woman, had marked exophthalmos, the eye being pushed forward and outward; tension was normal; vision was zero. The optic nerve was perfectly white. The impression gained from examination was that the anteroposterior diameter was shortened. The diagnosis was fibroma of the optic nerve. The eye was prominent. The tumor was removed after a tenotomy of the superior rectus and external rectus muscles, which were afterward sewed back in place, and an effort was made to save the globe and also to watch the results. On account of loss of the nerves severed, keratitis became well established, followed by ulceration of the cornea due to marked hypotony. The eye grew soft rapidly. This tension was slow to recover and the healed cornea left a dense scar. There was no loss of motion of the globe and the eye looked fairly well. Later on the globe developed intra-ocular tension, becoming very painful, and it was necessary to remove it. The patient now wears a glass eye.

MESOBLASTIC TUMORS; ORBITAL SARCOMAS

Case 16.—Mrs. M., seen Aug. 1, 1910, had a tumor producing exophthalmos. At operation, the internal rectus was tenotomized and a small tumor was removed, near the optic foramen close to the optic nerve, evidently growing from the intramuscular septums. The pathologist reported melanosarcoma. The patient returned, Dec. 26, 1911, approximately eighteen months later, with protrusion of the eye and evidence of return of the tumor, at which time I ligated and excised all the branches of the external carotid on each side and completely exenterated the globe. The patient was observed many times and had roentgen treatments. There was evidence of bony enlargement deep in the orbit, which was covered with skin. March 10, 1915, the x-rays were again used on account of evidence of tumor commencing in the bone. This patient lived in the country; the growth advanced into the brain and she died some months later.

Case 17.—Mrs. A., seen in 1910, had a sarcoma of the orbit involving the soft structures beneath the frontal bone on the temporal side. The tumor was removed, and the external carotid arteries and branches on each side were ligated and excised. The eyeball was saved. The patient was reported alive but blind in the left eye in 1914. I was unable to locate her later but am certain that she died.

Case 18.—G., a man, with orbital sarcoma, was operated on, May 6, 1912. March 23, 1915, the patient was still living, but he died in the latter part of that year. Marked exophthalmos was present at the time of operation. The tumor had destroyed the sight of his right eye, and the optic nerve on the nasal half of his left eye was definitely choked for about 6 diopters, there being no vision to the temporal side; whatever vision he had was from the temporal half of the nerve of the left side. The arterial trees on each side of the external carotid were excised and ligated. A complete exenteration was done and it is remarkable that the patient lived as long as he did, the tumor having already involved the bone.

Case 19.—Miss B., aged 16, seen Oct. 12, 1922, had a tumor growing back of the right eye. The eye was pushed well out, and a large tumor was located on the inner side of the orbit beneath the frontal bone. The condition dated back nine years following an attack of the grip, when protrusion was noticed. There were no constitutional symptoms referable to the eye. For a period of five years there was a marked protrusion of the eyeball; then a hard mass began to form, which continued to grow and enlarged until the patient stated that it had grown over the eyeball. She did not complain of symptoms other than headache.

Vision in the right eye was 20/200 when the lid was lifted; in the left, 20/40. The visual field was normal in each eye.

A diagnosis of fibrosarcoma was made. The postoperative laboratory diagnosis was "endothelioma involving the orbit," expressed in different terms.

At operation, ligation and excision of all branches of the carotid on each side was done. Fibrosarcomatous tissue underlying and closely interwoven with the skin was removed. The eyeball was saved until laboratory study of the tissue could be made, the slow growth of the tumor suggesting conservatism.

The specimen consisted of a tumor mass 5 by 33 by 23 cm. together with a small fragment of similar tumor tissue and two small lymph nodes, the larger of which was 0.6 cm. in diameter. The tumor surface was irregular and nodular. The mass cut with moderate resistance and was grayish, translucent on its cut surface, with a yellowish area near the periphery.

Microscopically, the tumor mass consisted chiefly of oval cells, having vesicular nuclei and resembling closely endothelial cells. There was a tendency everywhere to the formation of compact masses of tumor cells having a roughly concentric arrangement. A few of the dense masses were hyalinized and a smaller number were calcified; mitotic figures were few. There was no invasion of the included lymph nodes.

XANTHOSARCOMA OR LIPOSARCOMA

Case 20.—Mrs. A. G. had a tumor of seven years' standing producing a marked exophthalmos, so that the slightest manipulation of the lids caused the eye to protrude as on a stem. The sinuses were clear. The blood count was normal. The field of vision in each eye was normal; blind spots were greatly increased on the affected side (right) with the appearance of choked disk. Refraction gave evidence of plus 3 diopters, which I considered the result of the tumor pressure on the posterior surface of the globe. The vision was 20/30 in the right eye and 20/15 in the left. Tension was 25 in the right eye and 16 in the left. The preoperative diagnosis was "benign tumor," possibly fibroma growing in the orbital cavity. The tumor was removed, March 19, 1929.

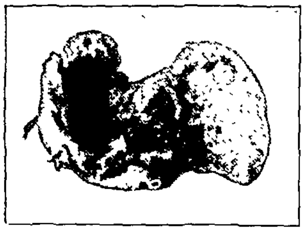

Fig. 11.—Fibroma of optic nerve.

A section of the tumor was examined by the pathologist, who reported that sections of the tumor removed from the orbit showed fibrous connective tissue; many of the cells had slight deposits of fat or lecithin; in some places there were groups of large polyhedral foam cells and in other places groups of cells resembling fat cells, except that they had prominent nuclei. A few giant cells were seen. Mitotic figures were not seen. The pathologic diagnosis was xanthoma of the orbit.

On my request, some of the section of the tissue was submitted to Dr. Ewing for examination and he made the following statement:

> "I have been seeing such orbital tumors as you send me for many years and have never known what to call them. I used the term 'endothelioma' for many years and then discarded it. The origin from fat tissue has come next on my list. It should make the tumor a xanthoma or liposarcoma. I do not think it is very malignant, but I have not followed the clinical history of my cases. The xanthomatous character of many cells is quite clear in your case. The yellow color favors an origin from fat tissue. You might stain it with sudan III. Xanthosarcoma and liposarcoma mean practically the same thing."

The tumor was encapsulated and, as I was about to remove it in toto, my assistant, attempting to keep it from oscillating, caught it with tissue forceps, rupturing the capsule. Although the tumor mass was removed, fluid appeared that seemed to come from a cyst in a tumor mass very much resembling brain tissue. Drainage was established with silkworm sutures; the eye was replaced, and when the patient was last seen the eye was on the same level, rotating in every direction. There was, however, some ptosis of the lid which has now disappeared. Vision in the eye was normal and the appearance of the choked disk had disappeared.

Under the title "Tumors of the Orbit of Doubtful Origin," Major Wright describes an identical tumor, except that he, in his manipulation, removed the tumor in pieces, and stated that there was no capsule. In every other respect, his description of the material of the tumor and the microscopic observations would suggest that he failed to appreciate that it was encapsulated.

ORBITAL TUMOR—GLAND TYPE

Case 21.—B., a man, seen in March, 1919, who had passed the railroad examination, did not know just when the eye commenced failing. There was no history of cancer in the family. One sister had died of tuberculosis eight years before. In June, 1921, he noticed that his left eye was lower and was being slowly pushed out. On account of exophthalmos and limited motion, the eye being pushed down and outward, a diagnosis of lacrimal tumor was made, Nov. 29, 1922. I removed the tumor and restored his eye to its normal level. and the patient was able to retain his position as a railroad man. Vision in the left eye was 5/200. There was marked paleness of the optic nerve and reduction of the field of vision. Following the operation, the vision arose to 15/200. Vision was normal in the right eye. The field was normal and has so remained as far as our records go.

The tumor mass was roughly oval and measured 3 by 2.8 by 2.2 cm. It was sharply defined, having a thin capsule, with the exception of an irregularly torn area on one surface. The sectioned surface consisted of banks of grayish tissue which anastomosed irregularly and between which were numerous small translucent areas, some of which contained yellowish regions pin-point in size. The tumor was relatively soft.

Microscopically the tumor consisted of clumps of small epithelial-like cells, some of which were arranged in the form of glands with pink-staining colloidal contents. Many dense masses of similar cells contained no definite gland spaces. The stroma of the tumor was abundant and edematous, with the myxomatous appearance usually seen in the common mixed tumors of the salivary glands. No evidence of a malignant condition was apparent anywhere in the sections examined.

The diagnosis was mixed tumor of the salivary gland type.

ORBITAL CYST

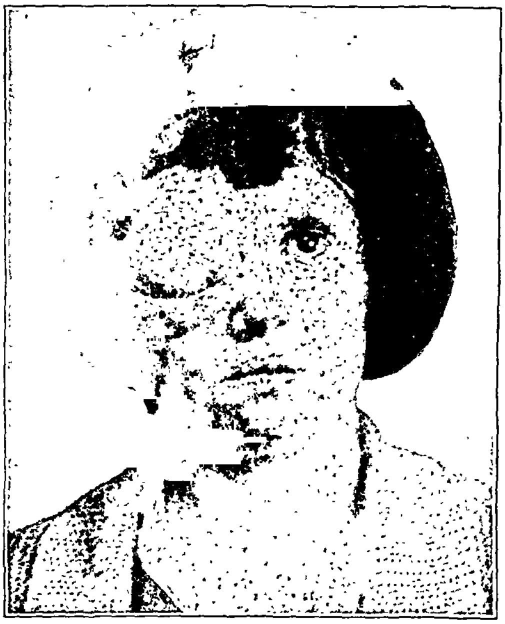

Fig. 12.—Endothelioma involving orbit.

Case 22.—B., a man, aged 28, had a tumor, causing exophthalmos, which had spontaneously lessened in size twice over a period of four years. He had no pain. The eye was pushed downward and outward. The preoperative diagnosis was cyst of the lacrimal gland. There was a history of the patient's having had a fall or blow over his head some years before. March 30, 1923, tension in the right eye was 15, and vision was 20/17, with some concentric reduction in the field of vision. The left eye did not register tension, and vision was 6/200. The field of vision was contracted concentrically and was definitely contracted for colors. The Wassermann reaction was negative.

The patient was seen by one of our ophthalmologists, who prescribed roentgen irradiation for a number of months, and had the patient's tonsils removed. He took a section for diagnosis, probably muscle, and said that it was an "innocent tumor" and that he would have to remove the eye for the purpose of getting the tumor; then instead he treated the patient with x-rays.

Microscopic study of this tumor definitely connected the history of trauma as the cause. The columnar epithelium possessing cilia originated from the mucous membrane of the cells underlying the orbital wall, and the bony growth was evidently a repair of the fractured bone which occurred in this locality years before. The cyst was the result of this misplacement of tissue, and the cystic wall had pressed on the lacrimal gland, destroying it, and had ruptured twice, spontaneously lessening the pressure on the eye, all of which was accounted for in the history of the case.

I removed the tumor, April 2, 1923, and the position of the eye became good. Observation over a long period revealed improved eyesight and no return of exophthalmos.

CONCLUSION

I wish especially to emphasize the value of injecting an eye specimen with solution of formaldehyde, as it aids materially in the clinician's macroscopic study of the eye without preventing further examination microscopically.
